1 Preamble
1.1 Editorial notes

This document was produced Sep 2017 to July 2018 by a joint working group with members from ZVEI SG ‘Models and Standards’ and Platform Industrie 4.0 working group WG1. The document was subsequently validated by the platform’s WG1.

For better readability, in compound terms the abbreviation "I4.0" is consistently used for "Industrie 4.0". Used on its own "Industrie 4.0" continues to be used.

1.2 Scope of this document

The aim of this document is to make selected specifications of the structure of the Administration Shell in such a way that information about assets and I4.0 components can be exchanged in a meaningful way between partners in a value creation network.

This part of this document therefore focuses on the question of how such information needs to be processed and structured. In order to make these specifications, the document formally stipulates a few structural principles of the Administration Shell. This part does not describe technical interfaces of the Administration Shell or other systems to exchange information, protocols or interaction patterns.

The document addresses the parallel DIN SPEC 92000 standardisation process for property value statements [15] and reflects important aspects in this document.

This document focuses on:
- Transport of information from one partner in the value chain to the next
- Administration Shell, submodels and their structures
- Identifiers
- Access rights and roles concept

This document currently features the version V1.0. It targets to be adequately complete and coherent to be used as basis for developments and as input for discussion with international standardization organisations and further cooperations.

A version V1.1 is intended to include additional mappings and features and should incorporate input from validation testbeds and international standardization.

The definitions in and the form of the document should be such that development departments in the value creation networks have enough detailed information to start work on internal systems for exchanging information and on corresponding databases.

1.3 Structure of the document

Chapter 2 summarises relevant, existing content from the standardisation of Industrie 4.0. In other words, this clause provides an overview and explains the motives, and is not absolutely necessary for an understanding of the subsequent definitions.

Chapter 3 stipulates sufficient structural principles of the Administration Shell in a formal manner in order to ensure an exchange of information between the Administration Shells. An excerpt of a UML diagram is drafted for this purpose. A more comprehensive UML discussion which does not set standards can be found in the annex.

Chapter 4 provides detailed definitions for the exchange of I4.0-compliant information in existing data formats like XML, AutomationML, OPC UA information models, JSON or RDF. An explanation is provided for each of these data formats stating how information is to be represented (metamodel), and an example of a representation is provided.

Chapter 5, 6, 7 describes the promotion of attribute based access models for information security.

Chapter 9 describes, how the information of one or more Administration Shell could be packed into a compound file format.
1.4 Principles of the work

The work is based on the following principle: as simple as possible, only absolutely necessary things are described.

For creating a detailed specification of the Administration Shell according to the scope of part 1 (→ 1.2), result papers published by Plattform Industrie 4.0, the Trilateral cooperation with France and Italy and international standardisation results were analysed and takes as source of requirements for the specification process. As many ideas as possible from the discussion papers were considered.

The partners represented in the Plattform Industrie 4.0 and associations such as the ZVEI, the VDMA, VDI/ VDE and Bitkom, ensure that there is broad sectoral coverage, both in process, hybrid and factory automation and in terms of integrating information technology (IT) and operational technology (OT).

Design alternatives were intensively discussed within the working group. An extensive feedback process with the so called "sounding board" of this document series, with the Plattform's working groups and with associated partners were engaged about the design alternatives and the final content of the specification.

Guiding principle for the specification was to provide detailed information, which can be easily implemented also by small and medium-sized enterprises.

1.5 Terms & Definitions

**Forward notice**

Definition of terms are only valid in a certain context. The current glossary applies to the context of this document.

**access control**

protection of system resources against unauthorized access; a process by which use of system resources is regulated according to a security policy and is permitted by only authorized entities (users, programs, processes, or other systems) according to that policy

→ [SOURCE: IEC TS 62443-1-1]

**application**

software functional element specific to the solution of a problem in industrial-process measurement and control

Note: An application may be distributed among resources and may communicate with other applications.

→ [SOURCE: IEC TR 62390:2005-01, 3.1.2]

**asset**

physical or logical object owned by or under the custodial duties of an organization, having either a perceived or actual value to the organization

Note: In the case of industrial automation and control systems, the physical assets that have the largest directly measurable value may be the equipment under control.

→ [SOURCE: IEC TS 62443-1-1:2009, 3.2.6]
asset administration shell (AAS)
standardized digital representation of the asset, corner stone of the interoperability between the applications managing the manufacturing systems. It identifies the Administration Shell and the assets represented by it, holds digital models of various aspects (submodels) and describes technical functionality exposed by the Administration Shell or respective assets.

Note: Asset Administration Shell and Administration Shell are use synonymously.

attribute
data element for the computer-sensible description of a property, a relation or a class

class
description of a set of objects that share the same attributes, operations, methods, relationships, and semantics

component
product used as a constituent in an assembled product, system or plant

concept
unit of knowledge created by a unique combination of characteristics

identifier (ID)
identity information that unambiguously distinguishes one entity from another one in a given domain

Note: There are specific identifiers, e.g. UUID Universal unique identifier, IEC 15418 (GS1).

instance
concrete, clearly identifiable component of a certain type

Note: It becomes an individual entity of a type, for example a device, by defining specific property values.
Note: In an object-oriented view, an instance denotes an object of a class (of a type).
**operation**

executable realization of a function

- Note: The term method is synonym to operation
- Note: an operation has a name and a list of parameters [ISO 19119:2005, 4.1.3]

**property**

defined characteristic suitable for the description and differentiation of products or components

- Note: The concept of type and instance applies to properties.
- Note: This definition applies to properties such as described in IEC 61360/ ISO 13584-42
- Note: The property types are defined in dictionaries (like IEC component Data dictionary or eCl@ss), they do not have a value. The property type is also called data element type in some standards.
- Note: The property instances have a value and they provided by the manufacturers. A property instance is also called property-value pair in certain standards.
- Note: Properties include nominal value, actual value, runtime variables, measurement values, etc.
- Note: A property describes one characteristic of a given object.
- Note: A property can have attributes such as code, version, and revision.
- Note: The specification of a property can include predefined choices of values.

**qualifier**

well-defined element associated with a property instance or submodel element, restricting the value statement to a certain period of time or use case

- Note: qualifier can have value associated

**variable**

software entity that may take different values, one at a time

**view**

projection of a model or models, which is seen from a given perspective or vantage point and omits entities that are not relevant to this perspective

**virtual representation**

totality of information of the Administration Shell, such as submodels, properties and complex data objects, covering digital models for the respective asset(s) for all applicable life-cycle phases
smart manufacturing
manufacturing approach, that improves its performance aspects with integrated and intelligent use of processes and resources in cyber, physical and human spheres to create and deliver products and services, which also collaborates with other domains within an enterprise’s value chains.

Note: Performance aspects include agility, efficiency, safety, security, sustainability or any other performance indicators identified by the enterprise.

Note: In addition to manufacturing, other enterprise domains can include engineering, logistics, marketing, procurement, sales or any other domains identified by the enterprise.

Note: this definition is, as of November 2018, under discussion within the ISO/IEC joint working group (JWG) 21. However, it gives a good indication and a citable source.

submodel
used to structure the virtual representation and technical functionality of an Administration Shell into distinguishable parts. Each submodel refers to a well-defined domain or subject matter. Submodels can become standardized and thus become submodels types. Submodels can have different life-cycles.

Note: The concept of type and instance applies to submodels.

submodel element
element suitable for the description and differentiation of assets

Note: extends the definition of properties
Note: could comprise operations, binary objects

system
interacting, interrelated, or interdependent elements forming a complex whole

[SOURCE: IEC TS 62443-1-1:2009, 3.2.123]

technical functionality
functionality of the Administration Shell that is exposed by an application programming interface (API) and that is creating added value to the respective assets(s).

Note: can consist of single elements, which are also known as functions, operations, methods, skills.

[SOURCE: according [18]]

template
specification of the common features of an object in sufficient detail that such object can be instantiated using it

Note: object can be anything that has a type

[SOURCE: according ISO/IEC 10746-2]
**type**

hardware or software element which specifies the common attributes shared by all instances of the type

2 Basic concepts and leading picture
2.1 Basic concepts

Many concepts for Industrie 4.0 and smart manufacturing are already existing. The most important ones are summarised in the informative Annex A.

2.2 Leading picture

The leading use case in this document is the exchange of an Asset Administration Shell including all its auxiliary documents and artifacts from one value chain partner to another. This is, in this document we do not deal with the use case of already deployed Asset Administration Shells running in a specific infrastructure but only with file exchange between partners.

Figure 1 Use Case File Exchange between Value Chain Partners

Figure 1 shows the overall picture. It depicts two value chain partners; "Supplier" is going to provide some products, "Integrator" is going to utilize this products in order to build a machine. Two kinds of Administration Shells are being provided; one for the asset being the type of a product, one for the assets being the actual product instances. "Supplier" and "Integrator" are forming two independent legal bodies (Figure 2).
The exchange of files needs to fulfill some requirements with respect to usability and security. There needs to be a bilateral agreement on security constraints to be fulfilled for the transfer and usage of the files. This is explained in more detail in chapter 5.

For usability, a container format for exchanging files is used and a corresponding structure is defined (see clause 6). This predefined structure helps the consumer to understand the content of the single files. This is important because an Asset Administration Shell specification can be spread across several files. Additionally, the container may contain auxiliary files references by the AAS or even executable code.
3  The Metamodel of the Administration Shell
3.1 Introduction

This clause specifies the information metamodel of the Asset Administration Shell. Before doing so some general aspect of the handling of asset types and instances are described (see clause 3.2 Types and Instances). Another very important aspect of the AAS is the identification aspect, see clause 3.3 Identification of entities.

The metamodel for security aspects of the Administration Shell is described in clause 5.

The legend for understanding the UML diagrams and the table specification of the classes are found in Annex B and Annex C.

3.2 Types and Instances

3.2.1 Life Cycle

Industrie 4.0 utilizes an extended understanding of asset, comprising elements such as factories, production systems, equipment, machines, components, produced products and raw materials, business processes and orders, immaterial assets (such as processes, software, documents, plans, intellectual property, standards), services and human personnel and more.

The RAMI4.0 model [3] features one, generalized life-cycle axis, which was derived from IEC 62890. The basic idea is to distinguish for all assets within Industrie 4.0 between possible types and instance. This makes it possible to apply the type-instance distinction for all elements such as material type/material instance, product type/product instance, machine type/machine instance and more. Business related information will be handled on the 'Business' layer of the RAMI4.0 model, as well, covering also order details and workflows, again with types/instances.

<table>
<thead>
<tr>
<th>Phase</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Type</td>
<td>Development</td>
</tr>
<tr>
<td></td>
<td>Usage / Maintenance</td>
</tr>
<tr>
<td>Instance</td>
<td>Production</td>
</tr>
<tr>
<td></td>
<td>Usage / Maintenance</td>
</tr>
</tbody>
</table>

Table 1 gives an overview of the different life cycles phases and the role of type and instance in these phases: The most important relationship is between asset types and asset instance. This relationship should be maintained throughout the life of the asset instances. By this relationship, updates to the asset types can be forwarded to the asset instances, either automatically or on demand.
The second class of relationships are feedback loops/intformation within the life-cycle of the asset type and instance. For product assets, for example, information on usage and maintenance of product instances can improve the manufacturing of products as also cause design improvements for the (next) product type.

The third class of relationships are feedforward/information exchange with assets of other asset classes. For example, sourcing information from business assets can influence design aspects of products; or, the design of the products affects the design of the manufacturing line.

A forth class of relationships are between asset of different hierarchy levels. For example, these could be the (dynamic) relationships between manufacturing stations and products being currently produced. These could be also the decompositions of production systems in physical, functional or safety hierarchies. By this class of relationships, automation equipment is explained as a complex, interrelated graph of automation devices and products, performing intelligent production and self-learning/optimization tasks.

3.2.2 Example

The following figure gives an example for handling of asset types and asset instances, handling some exemplary information as well. Further explanation will follow in the next clauses.

**Figure 3 Exemplary types and instances of assets represented by multiple AAS**

There shall be a concrete asset type of a temperature sensor and two uniquely identifiable physical temperature sensors of this type. The intention is to provide a separate AAS for the asset type as well as for every single asset instance.

In the example the first sensor has the unique ID “0215551AA_T1” and the second sensor has the unique ID “0215551AA_T2”. The AAS for the first sensor has the unique URL “www.T1.com” and the AAS for the second sensor has the unique URL “www.T2.com”. The kind for both is “Instance”. The example shows that the measured temperature at operation time of the two sensors is different: for T1 it is 60 °C, for T2 it is 100 °C. For the time-being we ignore the relationship “derivedFrom” of the two AAS “T1” and “T2” with AAS “www.T0215551AA.com”.

Note: for the distinction of ‘type’ and ‘instance’, the term ‘kind’ is used in this document.

Note: For an illustration of the second/third class of relationships confer the NIST model, as well.
These two asset instances do have a lot of information they share: the information of the asset type (in this example a sensor type). For this asset type an own AAS is created. The unique ID for this AAS is “www.T0215551AA.com”, the unique id of the sensor type is “0215551AA”. The kind in this case is “Type” and not “Instance”. The information that is the same for all instances of this temperature sensor type is the ProductClass (“Component”), the manufacturer (“Bosch”) and the English Description “=‘precise and fast temperature measurement’” as well as the value range “-40 °C / 140 °C”.

Now the two AAS of the two asset instances may refer to the AAS of the asset type “0215551AA” using the relationship attribute “derivedFrom”.

3.2.3 Metamodel of Asset Administration Shell Types and Instances

In the previous clause type and instances of assets were explained. Obviously the question then comes up how to harmonize AAS as well as AAS types. In our example it can be seen that the attributes “assetId” and “kind” as well as the global identifier (id, represented as name of the class) are present for all AAS. However, if there is no standard, it is not clear that the semantics of “id”, “assetId” and “kind” are the same and it is not clear, which of the attributes are mandatory and which are specific for the asset (type or instance). This is illustrated in Figure 4.

This is the task of this document: The definition of a metamodel that defines which attributes are mandatory and which are optional for all AAS. The Platform Industrie 4.0 metamodel for AssetAdministration Shells is defined in clause 3.
3.3 Identification of entities

3.3.1 Overview

Identifiers are needed according to [4] for the unique identification of many different entities within the domain of smart manufacturing. For this reason, they are a fundamental element of a formal description of the Administration Shell. Especially, identification is at least required for:

- Asset Administration Shells,
- assets,
- submodel instances and submodel types,
- property definitions/concept descriptions in external repositories, such as eCl@ss or IEC CDD

Identification will take place for two purposes:

1. to uniquely distinguish all entities of an Administration Shell, and
2. to relate entities to external definitions, such as submodel types and property definitions, in order to bind a semantics to these data and functional entities of an Administration Shell.

3.3.2 What Identifiers exist?

In [4], [20], two standard-conforming global identification types are defined:

(a) **IRDI** - ISO29002-5, ISO IEC 6523 and ISO IEC 11179-6 [20] as an Identifier scheme for properties and classifications. They are created in a process of consortium-wise specification or international standardisation. To this end, users sit down together and feed their ideas into the consortia or standardisation bodies. Properties in ISO, IEC help to safeguard key commercial interests. Repositories like eCl@ss and others make it possible to standardise a relatively large number of Identifiers in an appropriately short time.
(b) **URI** - URI and URL as identification of assets, Administration Shells and other (probably not standardised, but globally unique) properties and classifications.

The following is also permitted:

(c) **Custom** - Internal custom Identifiers such as GUIDs (globally unique Identifiers), which a manufacturer can use for all sorts of in-house purposes within the Administration Shell.

This means that the URIs/URLs and internal custom Identifiers can represent and communicate manufacturer-specific information and functions in the Administration Shell and the 4.0 infrastructure just as well as standardised information and functions. One infrastructure can serve both purposes.

Besides the global Identifiers there are also Identifiers that are unique only within a defined namespace, typically its parent element. These Identifiers are also called local identifiers. Example: Properties within a submodel have local identifiers.

### 3.3.3 Identifiers for Assets and Administration Shells

For the domain of smart manufacturing, the assets need to be identified worldwide unique [4] [20] by the means of identifiers (IDs). The Administration Shell has a unique ID, as well.

**Figure 5 The Administration Shell needs a unique Identifier, as well as each of the asset being described. Modified figure from [4]**

An Administration Shell represents exactly one asset, with a unique asset ID. In a batch based production, the batches will become the asset and will be described by a respective Administration Shell. If a set of assets shall be described by an Administration Shell, a unique ID for the composite asset needs to be created [12].
The ID of the asset needs to comply the restrictions for global Identifiers according [4] [20]. If the asset is featuring further identifications, serial numbers and such, there are not to be confused with the unique global Identifiers of the asset itself\(^1\).

### 3.3.4 Which Identifiers to use for which entities

Not every Identifier is applicable for every entity of the UML model; the following table therefore puts constraints on the various entities, which implement "Identifiable” or "hasSemantics”. Attributes relate to the metamodel in clause 3.4.

#### Table 2 Identifiables, attributes and allowed identifiers

<table>
<thead>
<tr>
<th>Identifiable</th>
<th>Attribute</th>
<th>Allowed Identifiers</th>
<th>Remarks</th>
</tr>
</thead>
<tbody>
<tr>
<td>Asset AdministrationShell</td>

</table>

| View Qualifier     | semanticId | IRDI, URI | links to the view definition in an external repository |
|--------------------|            |           |                                                     |
|                    | idShort    | string    | mandatory                                            |
|                    | semanticId | IRDI, URI, Internal | Links to the qualifier type definition in an external repository |

### 3.3.5 How are new Identifiers created?

Following the different identification types from clause 3.3.3, it can be stated:

(a) IRDIs are assumed to be already existing by an external specification and standardisation process, when it comes to the creation of a certain Administration Shell. For bringing such IRDI Identifiers into life, refer to clause 4 of the document [4].

(b) URIs and URLs can easily be formed by developers themselves, also on the fly when creating a certain Administration Shell. All that is needed is a valid URL hostname, for example of the company, and to make sure that the way the domain (e.g. www.festo.com) is organised ensures that the path behind the host name is reserved in a semantically unique way for these Identifiers. In this way, each developer can create an arbitrary URI or URL by combining the host name and some chosen path, which only needs to be unique in the developer’s organisation.

(c) Custom identifiers can also be easily formed by developers themselves. All that is necessary is for a corresponding programmatic functionality to be retrieved. It is necessary to ensure that internal custom Identifiers can be clearly distinguished from (a) or (b).

(d) Local identifiers can also be created on the fly. They have to be unique within their namespace, usually defined by the parent relationship.

3.3.6 Best practice for creating URI Identifiers

The approach for semantics and interaction for I4.0 components [17] suggests the use of the following structure for URIs\(^3\), which is slightly modified here. Idea is to always structure URI following a scheme of different elements:

<table>
<thead>
<tr>
<th>Table 3 Proposed structure for URIs</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Element</strong></td>
</tr>
<tr>
<td>Organisation</td>
</tr>
<tr>
<td>Organisational sub unit/Document / Document sub unit</td>
</tr>
<tr>
<td>Submodel / Domain-ID</td>
</tr>
<tr>
<td>Version</td>
</tr>
<tr>
<td>Revision</td>
</tr>
<tr>
<td>Property / Element-ID</td>
</tr>
<tr>
<td>Instance number</td>
</tr>
</tbody>
</table>

In the table, syntax component "A" refers to authority of RFC 3986 (URI) and namespace identifier of RFC 2141 (URN); "P" refers to path of RFC 3986 (URI) and namespace specific string of RFC 2141 (URN).

Using this scheme, valid URNs and URLs can be created, both being URIs. For the use of Administration Shells, URLs are preferred, as functionality (such as REST services) can be bound to the Identifiers, as well. Examples of such Identifiers are given in Table 4.

<table>
<thead>
<tr>
<th>Table 4 Example URN and URL-based Identifiers of the Administration Shell</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Identifier</strong></td>
</tr>
</tbody>
</table>
| Administration Shell ID| ID of the Administration Shell| Basis| urn:zvei:SG2:aas:1:1:demo11232322  
http://www.zvei.de/SG2/aas/1/1/demo11232322 |
| Submodel ID (Type)| Identification of type of submodel| Selected submodels are basis, others free| urn:GMA:7.20:contractnegotiation:1:1  
http://www.vdi.de/gma720/contractnegotiation/1/1 |
| Submodel ID (Instance)| Identification of the instance of the submodel| Free| urn:GMA:7.20:contractnegotiation:1:1#001  
http://www.vdi.de/gma720/contractnegotiation/1/1#001 |

\(^3\) URLs are also URIs
### 3.3.7 Creating a submodel instance based on an existing submodel type

In order to instantiate an existing submodel type, there should be a public specification of the submodel type, e.g. via publication by Plattform Industrie 4.0. As a special case, instantiating a submodel from a non-public submodel type, such as a manufacturer specification, is also possible.

As of November 2018, there are no finally published standardized submodel types available, but some examples are described in [6], which provides simple tables listing properties in a predefined hierarchy.

In each submodel type, the **Identifiers of property definitions to be used as semantic references are already predefined**. An instantiation of such submodel merely has to create properties with a semantic reference to the property definitions and attach values to these properties.

In such case, the Identifier for the existing submodel type is also predefined, probably as a URL, and is to be used as semantic reference for the submodel instance.

What remains is to create an Identifier of the submodel instance itself, which is in the regular case and URI/ URL.

---

**Note:** for maintaining integrity over multiple Administration Shells, appropriate referencing (derivedFrom) between submodel instances and submodel types has to occur, as well as for submodel instances of interlinked asset types and instances. A possible framework could then monitor and synchronize changes to the value statements of the submodel instances according to user requirements (automatic synchronization is not always desired).

---

### 3.3.8 Can new or proprietary submodels be formed?

It is in the interest of Industrie 4.0 for as many submodels as possible, including free and proprietary submodels, to be formed (→ [4], “Free property sets”). A submodel can be formed at any time for a specific Administration Shell of an asset. For this purpose, the provider of the Administration Shell can form in-house Identifiers for the type and instance of the submodel in line with Section 3.3.5. All I4.0 systems are called on to ignore submodels and properties that are not individually known, and simply to “overlook” them. For this reason, it is always possible to deposit proprietary – e.g. manufacturer-specific or user-specific – information, submodels or properties in an Administration Shell.

**Note:** it is in the intention of the Administration Shell, that proprietary information is included as well. For example to link to company-wide identification schemes or information required for company-wide data processing. By this, a single infrastructure can be used to transport standardized and proprietary information at the same time; this conveys the introduction (and later standardization) of new information elements as well. **Note:** if a submodel instance is formed without a clear relation to a submodel type or semantic definition, this will be of limited use for other users/ accessing systems of the Administration Shell, as these cannot grasp the semantic context of the data contained.
3.3.9 Usage of short ID for identifiable entities

The Administration Shell fosters the use of worldwide unique identifiers to a large degree. However, in some cases, this may lead to inefficiencies. An example might be referring to a property, which is part of a submodel which is part of an Administration Shell and each of these identified by global Identifiers [4]. For example, in an application featuring a resource oriented architecture (ROA), a worldwide unique resource locator (URL) might be composed of a series of segments, which in turn do not need to be worldwide unique:

Figure 6 Motivation of exemplary identifiers and idShort

In order to allow such efficient addressing of entities by an API of an Administration Shell, idShort is provided for a set of classes of the metamodel, which inherit from abstract class Referable, in order to refer to such dependent entities (→ 3.4). However, an external system addressing resources of an Administration Shell is required to check the respective semantics by asserting semanticId first, before accessing entities by id or idShort (→ 3.5.2).

3.4 Overview Metamodel of the Administration Shell

In this clause an overview of the main concepts of the AssetAdministration Shell metamodel is presented. The main parts of an Asset Administration Shell (AAS) is the asset it is representing as well as the submodels. Optionally, dictionaries and views may be part of the AAS. A dictionary contains so-called concept descriptions. For details see clause 3.5.3. Views define a set of elements selected for a specific stakeholder. For details see clause 3.5.11. An AAS represents exactly one asset. Asset types and asset instances are distinguished by setting the attribute “kind”. For details see clause 3.5.2.3.

Note: the UML modelling uses so-called abstract classes for denoting reused concepts like “HasSemantics”, “Qualifiable” etc.

In case of an AAS of an instance asset, a reference to the AAS representing the corresponding asset type or another asset instance is was derived from may be added (derivedFrom). The same holds for AAS of an asset type: also types can be derived from other types.

An asset typically may be represented by several different identification properties like for example the serial number, its RFID code etc. Such local identification properties are defined in the asset identification submodel (assetIdentificationModel). For details see clause 3.5.4.

AASs, assets, submodels and concept descriptions need to be globally uniquely identifiable (Identifiable). Other elements like for example properties, single local dictionaries just need to be referable within the model and thus only need a local identifier (idShort from Referable). For details on identification see Chapter 3.3 Identification of entities. For details on Identifiable and Referable see 3.5.2.1.

Submodels consist of a set of submodel elements. Submodel elements may be qualified by a so-called Qualifier. For details see clause 3.5.5.

There are different subtypes of submodel elements like properties, operations, collections etc. For details see clause 3.5.5. A typical submodel element is shown in the overview figure: a property. A property is a data submodel element that has a value of simple type like string, date etc. For details on properties see clause 3.5.7.

Every submodel element needs a semantic definition (semanticId in HasSemantics). The submodel element might either refer directly to a corresponding semantic definition provided by an external reference (e.g. to an eCl@ss or IEC CDD property definition) or it may reference a submodel element of kind = Type that defines the semantics of submodel elements of kind = Instance. For details see clause 3.5.2.5.

The AAS itself can also define its own dictionary that contains semantic definitions of its submodel elements. These semantic definitions are called concept descriptions (ConceptDescription). It is optional whether an AAS defines its own concept dictionary (ConceptDictionary) or not. For details see clause 3.5.12.

The concept dictionary may contain copies of property definitions of external standards. In this case a semantic definition to the external standard shall be added (isCaseOf). isCaseOf is a more formal definition of sourceOfDefinition that is just text.

Note: in this case most of the attributes are redundant because these are defined in the external standard. It is about usability to add attributes for information like preferredName, unit etc. Consistency w.r.t. to the referenced submodel element definitions should be ensured by corresponding tooling.

The concept dictionary may also contain proprietary definitions. In this case the provider of the AAS shall be aware that no interoperability with other AAS can be ensured.

Data Specification Templates (hasDataSpecification) can be used to define which attributes (besides those predefined by the metamodel) are used to define a submodel element or a concept description. For the concept description of properties typically the Data Specification Template following IEC 61360 is used. For denoting recommended Data Specification Templates to be used the <<template>>-dependency is used. For details see clause 3.5.2.6.
Some Data Specification Templates like the template for IEC 61360 property definitions (DataSpecification_IEC61360) are explicitly predefined and recommended to be used by the Plattform Industrie 4.0. For details see clause 3.6.2. If proprietary templates are used, again, interoperability with other AAS cannot be ensured.

Besides submodel elements including properties and concept descriptions also other identifiable elements may use additional templates (HasDataSpecification). For details see clause 3.5.2.7.

Submodel elements and the submodels themselves may have additional qualifiers (Qualifiable). Per Qualifiable there might be more than one qualifier. For details see clause 3.5.2.6.

Additionally, Views can be defined within an AAS. Views may consist of any elements that are referable (containedElement). A “Safety View”, for example, contains all properties or operations that are safety relevant and need special treatment. For details see clause 3.5.11. A View definition can also be used in different life cycle stages. For example, there could be a view for engineering and all referenced artefacts are deleted before delivering the AAS to the customer.

For every AAS security aspects need to be considered (security). In this document the aspect of access control is covered in more detail. So-called access permission rules are defined, that define which permission a specific authenticated subject has on which object. For details see clause chapter.

Figure 8 gives a complete picture of all elements defined in the metamodel excluding security. Security is found in clause 5.3.

### 3.5 Metamodel Specification Details: Designators

#### 3.5.1 Introduction

In this clause the classes of the metamodel are specified in detail. In Annex B the template used to describe the classes and relationships is explained. In Annex D some of the diagrams are shown together with all its inherited attributes to give a complete overview.

For understanding the specifications, it is crucial to understand the common attributes first (clause 3.5.2). They are reused throughout the specifications of the other classes (“inherits from”) and define important concepts like identifiable, qualifiable etc. They are abstract, i.e. there is no object instance of such classes.

#### 3.5.2 Common attributes

##### 3.5.2.1 Identifiables & Referables

Figure 9 Metamodel for Identifiables and Referables
The metamodel distinguishes between elements that are identifiable, referable or none of both. An identifiable element as a globally unique identifier (Identifier). Referable elements can be referenced but for doing so the context of the element is needed. A referable has a short unique identifier (idShort) that is unique just in its context, its name space. An identifiable is also referable but there are elements that are not referable: they are just attributes of a referable. Identifiables may have administrative information like version etc.

A name space is defined as follows in this context: The parent element an element is part of and that is either referable or identifiable is the name space of the element. Examples: A submodel is the name space for the properties contained in it. The name space of a submodel element being contained in a submodel element collection is the submodel element collection. However, for identifiables the name space is not important since identifiables per definition have a global identifier.

<table>
<thead>
<tr>
<th>Class:</th>
<th>Referable &lt;&lt;abstract&gt;&gt;</th>
</tr>
</thead>
<tbody>
<tr>
<td>Explanation:</td>
<td>An element that is referable by its idShort. This id is not globally unique. This id is unique within the name space of the element.</td>
</tr>
<tr>

<td></td>
<td></td>
</tr>
</tbody>
</table>
3.5.2.2 Identifier

Information about identification can be found in Chapter 3.3 Identification of entities. In Chapter 3.3.4 constraints and recommendation on when to use which type of Identifier can be found.

Examples for Identifiers can be found in Chapter 3.3.3 Identifiers for Assets and Administration Shells.
See Chapter 3.5.2.2 Identifier for information which identifier types are supported.
IRDI | IRDI according to ISO29002-5 as an Identifier scheme for properties and classifications.
---|---
URI | URI
Custom | Custom identifiers like GUIDs (globally unique Identifiers)

### 3.5.2.3 Has Kind Type or Instance

**Figure 11 Metamodel for HasKind**

<table>
<thead>
<tr>
<th>Class:</th>
<th>HasKind</th>
</tr>
</thead>
</table>

**Explanation:**
An element with a kind is an element that can either represent a type or an instance.
Default for an element is that it is representing an instance.

<table>
<thead>
<tr>
<th>Inherits from:</th>
<th>--</th>
</tr>
</thead>
</table>

<table>
<thead>
<tr>
<th>Attribute (*mandatory)</th>
<th>Explanation</th>
<th>Type</th>
<th>Kind</th>
<th>Card.</th>
</tr>
</thead>
<tbody>
<tr>
<td>Kind</td>
<td>Kind of the element: either type or instance. Default Value = Instance</td>
<td>Kind</td>
<td>attr</td>
<td>0..1</td>
</tr>
</tbody>
</table>

The kind enumeration is used to denote whether an element is of kind Type or Instance.

<table>
<thead>
<tr>
<th>Enumeration:</th>
<th>Kind</th>
</tr>
</thead>
</table>

**Explanation:**
Enumeration for denoting whether an element is a type or an instance.

<table>
<thead>
<tr>
<th>Inherits from:</th>
<th>--</th>
</tr>
</thead>
</table>

<table>
<thead>
<tr>
<th>Literal</th>
<th>Explanation</th>
</tr>
</thead>
</table>
| Type | hardware or software element which specifies the common attributes shared by all instances of the type  
| Instance | concrete, clearly identifiable component of a certain type  
Note: It becomes an individual entity of a type, for example a device, by defining specific property values.  
Note: In an object oriented view, an instance denotes an object of a class (of a type).  

For more information of types and instances see 3.23.2 Types and Instances.
3.5.2.4 Administrative Information

Figure 12 Metamodel for Administrative Information

Every *Identifiable* may have administrative information. Administrative information includes for example:

- Information about the version of the element
- Information about who created or who made the last change to the element
- Information about the languages available in case the element contains text, for translating purposes also the master or default language may be defined

In the first version of the AAS metamodel only version information as defined by IEC 61360 is defined. In later versions additional attributes may be added.

Version corresponds in principle to the `version_identifier` according to IEC 62832 but is not used for concept identifiers only (IEC TS 62832-1) but for all identifiable elements. Version and revision together correspond to the version number according to IEC 62832.

*AdministrativeInformation* allows the usage of templates (*HasDataSpecification*) but there are no predefined templates in this version of the metamodel.

**Note:** Some of the administrative information like the version number might need to be part of the identification.

<table>
<thead>
<tr>
<th>Class:</th>
<th>AdministrativeInformation</th>
</tr>
</thead>
<tbody>
<tr>
<td>Explanation:</td>
<td>Administrative metainformation for an element like version information.</td>
</tr>
<tr>
<td>Inherits from:</td>
<td>HasDataSpecification</td>
</tr>
</tbody>
</table>

<table>
<thead>
<tr>
<th>Attribute (*=mandatory)</th>
<th>Explanation</th>
<th>Type</th>
<th>Kind</th>
<th>Card.</th>
</tr>
</thead>
<tbody>
<tr>
<td>version</td>
<td>Version of the element.</td>
<td>string</td>
<td>attr</td>
<td>0..1</td>
</tr>
<tr>
<td>revision</td>
<td>Revision of the element.</td>
<td>string</td>
<td>attr</td>
<td>0..1</td>
</tr>
</tbody>
</table>

Constraint AASd-005: A revision requires a version. This means, if there is no version there is no revision neither.
3.5.2.5 Semantic References

Figure 13 Metamodel for Semantic References (HasSemantics)

Class: HasSemantics <<abstract>>

Explanation: Element that can have a semantic definition.

Inherits from: --

<table>
<thead>
<tr>
<th>Attribute (*=mandatory)</th>
<th>Explanation</th>
<th>Type</th>
<th>Kind</th>
<th>Card.</th>
</tr>
</thead>
<tbody>
<tr>
<td>semanticId</td>
<td>Identifier of the semantic definition of the element. It is called semantic id of the element. The semantic id may either reference an external global id or it may reference a referable model element of kind=Type that defines the semantics of the element. Note: In many cases the idShort is identical to the short name within the semantic definition as referenced via this semantic id.</td>
<td>Reference</td>
<td>attr</td>
<td>0..1</td>
</tr>
</tbody>
</table>

3.5.2.6 Qualifiables

Figure 14 Metamodel Qualifiables and Constraints
For qualifiable elements additional qualifiers may be defined. For details on qualifiers and for predefined standardized qualifier types see IEC 62569-1. For example, a level qualifier defining the level type minimal value, maximum value, typical value and nominal value can be found in IEC 62569-1. Additional qualifier types are planned to be defined in the ongoing work of DIN SPEC 92000 like for example expressions semantics and expression logic.

If there are no predefined qualifier types or the additional qualification is quite complex then instead of a set of qualifiers also a formula can be defined.

In Figure 15 an example for a formula depending on the property “Status” is shown. Up to now no formula language is defined for the AAS.

**Figure 15 Example Formula**

</tr>
</tbody>
</table>

#### 3.5.2.7 Template for Data Specification

**Figure 16 Metamodel for HasDataSpecification**

![Diagram of HasDataSpecification](attachment:image)

### Class: HasDataSpecification <<abstract>>

**Explanation:** Element that can have data specification templates. A template defines the additional attributes an element may or shall have.

**Inherits from:** --

<table>
<thead>
<tr>
<th>Attribute</th>
<th>Explanation</th>
<th>Type</th>
<th>Kind</th>
<th>Card.</th>
</tr>
</thead>
<tbody>
<tr>
<td>hasDataSpecification</td>
<td>Global reference to the data specification template used by the element.</td>
<td>Reference</td>
<td>aggr</td>
<td>0..*</td>
</tr>
</tbody>
</table>
An Administration Shell is uniquely identifiable since it inherits from Identifiable.

The derivedFrom attribute is used to establish a relationship between two AssetAdministration Shells that are derived from each other. For more detailed information on the derivedFrom concept see clause 3.2 Types and Instances.

<table>
<thead>
<tr>
<th>Attribute</th>
<th>Explanation</th>
<th>Type</th>
<th>Kind</th>
<th>Card.</th>

<tr>
<td>Inherits from:</td>
<td>HasDataSpecification; Identifiable; HasKind</td>
</tr>
<tr>
<td>Attribute (*=mandatory)</td>
<td>assetIdentificationModel</td>
</tr>
<tr>
<td>Explanation</td>
<td>A reference to a Submodel that defines the handling of additional domain specific (proprietary) identifiers for the asset like e.g. serial number etc.</td>
</tr>
<tr>
<td>Type</td>
<td>Submodel</td>
</tr>
<tr>
<td>Kind</td>
<td>ref*</td>
</tr>
<tr>
<td>Card.</td>
<td>0..1</td>
</tr>
</tbody>
</table>
3.5.5 Submodel and Submodel Element Attributes

Figure 19 Metamodel for Submodel

A submodel instance can reference the submodel type it was derived from. Formulated in a technical way: semanticId of a Submodel with kind=Instance may refer to a Submodel of kind=Type (kind inherited via HasKind).

A submodel can be qualified (Qualifiable).

Submodel element are qualifiable elements, i.e. one or more qualifier may be defined for each of them.

Submodels and submodel elements may also have data specification templates defined for them. A template might for example be defined to mirror some of the attributes like preferredName and unit of a property definition if the AAS does not contain a corresponding concept description. Otherwise there only is the property definition referenced by semanticId available for the property: the lookup of the attributes has to be realized online in a different way and is not available offline.
In case the submodel is of kind=Type then the submodel elements within the submodel are presenting submodel element types. In case the submodel is of kind=Instance then its submodel elements represent submodel element instances.

<table>
<thead>
<tr>
<th>Class:</th>
<th>SubmodelElement &lt;&lt;abstract&gt;&gt;</th>
</tr>
</thead>
<tbody>
<tr>
<td>Explanation:</td>
<td>A submodel element is an element suitable for the description and differentiation of assets.</td>
</tr>
<tr>
<td></td>
<td><strong>NOTE:</strong> The concept of type and instance applies to submodel elements. Properties are special submodel elements. The property types are defined in dictionaries (like the IEC Common Data Dictionary or eC1@ss), they do not have a value. The property type (kind=Type) is also called data element type in some standards. The property instances (kind=Instance) typically have a value. A property instance is also called property-value pair in certain standards.</td>
</tr>
<tr>
<td>Inherits from:</td>
<td>HasDataSpecification; Referable; Qualifiable; HasSemantics; HasKind</td>
</tr>
</tbody>
</table>

<table>

<th>Explanation</th>
<th>Type</th>
<th>Kind</th>
<th>Card.</th>
</tr>
</thead>
</table>

Figure 21 Metamodel for Data Elements and its Subtypes
3.5.6 Overview of Submodel Element Types

Submodel elements include data properties as well as operations, events and other elements needed to describe a model for an asset (see Figure 20).

In this version of the metamodel the focus is on the data properties.

3.5.7 Data Element Attributes

Data Elements include properties and file handling and reference elements, see Figure 21.

The following categories are defined for properties:

<table>
<thead>
<tr>
<th>Category</th>
<th>Applicable to</th>
<th>Explanation:</th>
</tr>
</thead>
<tbody>
<tr>
<td>CONSTANT</td>
<td>Property</td>
<td>A constant property is a property with a value that does not change over time.</td>
</tr>
<tr>
<td></td>
<td></td>
<td>In eCl@ss this kind of category has the category “Coded Value”.</td>
</tr>
<tr>
<td>PARAMETER</td>
<td>Property</td>
<td>A parameter property is a property that is once set and then typically does not change over time.</td>
</tr>
<tr>
<td></td>
<td></td>
<td>This is for example the case for configuration parameters.</td>
</tr>
<tr>
<td>VARIABLE</td>
<td>Property</td>
<td>A variable property is a property that is calculated during runtime, i.e. its value is a runtime value.</td>
</tr>
</tbody>
</table>

### Property

**Class:** DataElement <<abstract>>

**Explanation:** A property is a data element that has a single value.

**Inherits from:** DataElement

</tr>
</tbody>
</table>
A media type (also MIME type and content type) [...] is a two-part Identifier for file formats and format contents transmitted on the Internet. The Internet Assigned Numbers Authority (IANA) is the official authority for the standardization and publication of these classifications. Media types were originally defined in Request for Comments 2045 in November 1996 as a part of MIME (Multipurpose Internet Mail Extensions) specification, for denoting type of email message content and attachments; [...] hence the name /MIME type.¹

---

Class: Blob

Explanation: A BLOB is a data element that represents a file that is contained with its source code in the value attribute.

Inherits from: DataElement

<table>
<thead>
<tr>
<th>Attribute (*=mandatory)</th>
<th>Explanation</th>
<th>Type</th>
<th>Kind</th>
<th>Card.</th>
</tr>
</thead>
<tbody>
<tr>
<td>value*</td>
<td>The value of the BLOB instance of a blob data element. Note: In contrast to the file property the file content is stored directly as value in the Blob data element.</td>
<td>BlobType</td>
<td>attr</td>
<td>0..*</td>
</tr>
</tbody>
</table>

mimeType* Mimetype of the content of the BLOB. The mimetype states which file extension the file has. Valid values are e.g. "application/json", "application/xls", "image/jpeg" The allowed values are defined as in RFC2046.

Class: File

Explanation: A File is a data element that represents a file via its path description.

Inherits from: DataElement

<table>
<thead>
<tr>
<th>Attribute (*=mandatory)</th>
<th>Explanation</th>
<th>Type</th>
<th>Kind</th>
<th>Card.</th>
</tr>
</thead>
<tbody>
<tr>
<td>value</td>
<td>Path and name of the referenced file (without file extension). The path can be absolute or relative. Note: The file extension is defined by using a qualifier of type &quot;MimeType&quot;.</td>
<td>PathType</td>
<td>attr</td>
<td>0..1</td>
</tr>
</tbody>
</table>

mimeType* Mimetype of the content of the File.

For handling of supplementary external files in exchanging AAS specification in aasx format see also clause 6.4 Conventions for the Asset Administration Shell package file format (AASX). An absolute path is used in the case that the file exists independently of the AAS. A relative path, relative to the package root should be used if the file is part of the serialized package of the AAS.

¹ Wikipedia.org, date: 2018-04-09
THE METAMODEL OF THE ADMINISTRATION SHELL

Class: ReferenceElement

Explanation: A reference element is a data element that defines a reference to another element within the same or another AAS or a reference to an external object or entity.

Inherits from: DataElement

Attribute (*=mandatory) | Explanation | Type | Kind | Card.
--- | --- | --- | --- | ---
value | Reference to any other referable element of the same of any other AAS or a reference to an external object or entity. | Reference | aggr | 0..1

For more information on references see clause 3.5.13.

3.5.8 Data Element Collection Attributes

Figure 22 Metamodel for Submodel Element Collections

Class: SubmodelElementCollection

Explanation: A submodel element collection is a set or list of submodel elements.

Inherits from: SubmodelElement

Attribute (*=mandatory) | Explanation | Type | Kind | Card.
--- | --- | --- | --- | ---
value | Submodel element contained in the collection. | SubmodelElement | aggr | 0..*
ordered | If ordered=false then the elements in the property collection are not ordered. If ordered=true then the elements in the collection are ordered. Default = false | boolean | attr | 0..1
### 3.5.9 Relationship Attributes

**Figure 23 Metamodel of Relationship Elements**

<table>
<thead>
<tr>

<th>Operation</th>
</tr>
</thead>
<tbody>
<tr>
<td>Explanation:</td>
<td>An operation is a submodel element with input and output variables.</td>
</tr>
<tr>
<td>Inherits from:</td>
<td>SubmodelElement</td>
</tr>
</tbody>
</table>

<table>
<thead>
<tr>
<th>Attribute (*=mandatory)</th>
<th>Explanation</th>
<th>Type</th>
<th>Kind</th>
<th>Card.</th>
</tr>
</thead>
<tbody>
<tr>
<td>in</td>
<td>Input parameter of the operation.</td>
<td>OperationVariable</td>
<td>agr*</td>
<td>0..*</td>
</tr>
</tbody>
</table>
### 3.5.11 View attributes

Figure 25 Metamodel of Views

![Diagram](image)

The large number of submodel elements within a submodel can be filtered by views, so that different user groups can only see relevant elements.

**Note:** According clause 1.5, views are a projection of submodel elements for a given perspective. They are not equivalent to submodels.
### 3.5.12 Concept Dictionary Attributes

#### Figure 26 Metamodel of Concept Dictionary

<table>
<thead>
<tr>
<th>Class:</th>
<th>ConceptDictionary</th>
</tr>
</thead>
<tbody>
<tr>
<td>Explanation:</td>
<td>A dictionary contains elements that can be reused.</td>
</tr>
<tr>
<td></td>
<td>The concept dictionary contains concept descriptions.</td>
</tr>
<tr>
<td></td>
<td>Typically a concept description dictionary of an AAS contains only concept descriptions of elements used within submodels of the AAS.</td>
</tr>
<tr>
<td>Inherits from:</td>
<td>Referable</td>
</tr>
<tr>
<td>Attribute (mandatory)</td>
<td>Explanation</td>
</tr>
<tr>
<td>conceptDescription</td>
<td>Concept description defines a concept.</td>
</tr>
</tbody>
</table>

<table>
<thead>
<tr>
<th>Class:</th>
<th>ConceptDescription</th>
</tr>
</thead>
<tbody>
<tr>
<td>Explanation:</td>
<td>The semantics of a property or other elements that may have a semantic description is defined by a concept description.</td>
</tr>
<tr>
<td></td>
<td>The description of the concept should follow a standardized schema (realized as data specification template).</td>
</tr>
<tr>
<td>Inherits from:</td>
<td>HasDataSpecification; Identifiable;</td>
</tr>
<tr>
<td>Attribute (mandatory)</td>
<td>Explanation</td>
</tr>
<tr>
<td>isCaseOf</td>
<td>Global reference to an external definition the concept is compatible to or was derived from.</td>
</tr>
<tr>
<td></td>
<td>Note: Compare to attribute is case of in ISO 13584-32</td>
</tr>
<tr>
<td></td>
<td>Reference</td>
</tr>
</tbody>
</table>

Different types of submodel elements require different attributes for describing the semantics of them. This is why a concept description has at least one data specification template associated with it. Within this template the attributes needed to define the semantics are defined.

See clause 3.6 for predefined data specification templates to be used.
3.5.13 Referencing in Asset Administration Shells

Figure 27 Metamodel for References and Keys

Note: References are used throughout the metamodel although not directly visible.

If an element is not a part of an element but just references this is denoted by an * behind the Type.

E.g. asset: Asset* means that asset: Reference with Key.type=Asset for the last Key in the Reference

---

<table>
<thead>
<tr>
<th>Class:</th>
<th>Reference</th>
</tr>
</thead>
</table>
| Explanation: | Reference to either a model element of the same or another AAs or to an external entity. 
A reference is an ordered list of keys, each key referencing an element. The complete list of keys may for example be concatenated to a path that then gives unique access to an element or entity. |
| Inherits from: | -- |
| Attribute (mandatory) | Explanation | Type | Kind | Card. |
| key | Unique reference in its name space. | Key | attr | 0..* |

<table>
<thead>
<tr>
<th>Class:</th>
<th>Key</th>
</tr>
</thead>
<tbody>
<tr>
<td>Explanation:</td>
<td>A key is a reference to an element by its id.</td>
</tr>
<tr>
<td>Inherits from:</td>
<td>--</td>
</tr>
</tbody>
</table>
### The Metamodel of the Administration Shell

<table>
<thead>
<tr>
<th>Class:</th>
<th>Key</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Attribute</strong> (*=mandatory)</td>
<td><strong>Explanation</strong></td>
</tr>
<tr>
<td>type*</td>
<td>Denote which kind of entity is referenced. In case type = GlobalReference then the element is a global unique id. In all other cases the key references a model element of the same or of another AAS. The name of the model element is explicitly listed.</td>
</tr>
<tr>
<td>local*</td>
<td>Denotes if the key references a model element of the same AAS (=true) or not (=false). In case of local = false the key may reference a model element of another AAS or an entity outside any AAS that has a global unique id.</td>
</tr>
<tr>
<td>value*</td>
<td>The key value, for example an IRDI if the idType=IRDI.</td>
</tr>
<tr>
<td>idType*</td>
<td>Type of the key value. In case of idType = idShort local shall be true. In case type=GlobalReference idType shall not be IdShort.</td>
</tr>
</tbody>
</table>

The enumeration “KeyElements” is a set of the following values:

- “GlobalReference”
- All class names of referables that are not identifiable (see enumeration ReferableElements in Figure 27)
- All class names of identifiables (see enumeration IdentifiableElements in Figure 27)

### 3.5.14 Types

#### 3.5.14.1 Predefined Basic Types

The predefined types used to define the metamodel use the names and the semantics of XML Schema Definition (XSD)⁵. Additionally the type “langString” with the semantics as defined in the Resource Description Framework (RDF)⁶ is used. “langString” is a string that can be provided in several languages, each.

---

⁵ see: [https://www.w3.org/XML/Schema](https://www.w3.org/XML/Schema)

⁶ see: [https://www.w3.org/TR/rdf11-concepts/](https://www.w3.org/TR/rdf11-concepts/)

<td>string</td>
</tr>
</tbody>
</table>

### 3.5.15 Templates, Inheritance, Qualifiers and Categories

On a first glance there seem to be some overlapping between the concept of data specification templates, inheritance, qualifiers and categories. In this clause the commonalities and differences are explained and hints for good practices are given.

In general extension of the metamodel by inheritance is allowed. As an alternative also templates might be used.

- Templates should only be used if different instances of the class follow different schemas and the templates for the schemas are not known at design time. Templates might also be used if the overall metamodel is not yet stable enough or a tool does support templates but not (yet) the complete metamodel.
- However: when using non-standardized proprietary data specification templates interoperability cannot be ensured and thus should be avoided whenever possible.
- In case all instances of a class follow the same schema then inheritance and/or categories should be used.
- Categories can be used if all instances of a class follow the same schema but have different constraints depending on its category. Such a constraint might specify that an optional attribute is mandatory for this category (like for example the unit that is mandatory for properties representing physical values). Realizing the same via inheritance would lead to multiple inheritance what is to be omitted.
- Qualifiers are used if the semantics of the element is the same independent of its qualifiers. It is only the quality or the meaning of the value for the element that differs.
3.6 Predefined Data Specification templates

3.6.1 Concept of Data Specification Templates

It is required that a data specification template has a global unique id so that it is can be referenced via HasDataSpecification.

A template consists of the DataSpecificationContent containing the additional attributes to be added to the element instance that references the data specification template and meta information about the template itself (this is why exemplary DataSpecification inherits from Identifiable). In UML these are two separated classes.

3.6.2 Predefined Templates for Property Descriptions

For the meaning of the attributes of the IEC61360 data specification template please refer to IEC 61360 and/or eCl@ss.

We recommend to refer to this data specification template via the id "www.admin-shell.io/DataSpecificationTemplates/DataSpecificationIEC61360" (in hasDataSpecification).
See Figure 31 for how data specification templates are related to concept descriptions (showing all inherited attributes as well). In a similar way templates for other elements in the information model can be defined and used.

**Figure 31 Overview Concept Descriptions and Data Specification Templates**
4 Mappings to data formats to share I4.0-compliant information
4.1 General

It should be possible to share I4.0-compliant information between different systems throughout the area covered by the entire RAMI4.0 model [1] [2]. OPC UA has been targeted as a format for information models in the domain of production operations, but there is a need for other formats for the other areas and the interrelationships between them.

This document describes the AssetAdministration Shell together with its submodels in different data formats:

Table 6 Distinction of different data format for the AAS

<table>
<thead>
<tr>
<th>Data format</th>
<th>Purpose / motivation</th>
</tr>
</thead>
<tbody>
<tr>
<td>OPC UA Information models</td>
<td>Access to all information of the administration data and sharing of live data within production operations. Access for higher-level factory systems to this information.</td>
</tr>
<tr>
<td>AutomationML</td>
<td>Sharing of type and instance information about assets, particularly during engineering. Transfer of this information into the operational phase (cf. OPC UA and the corresponding mapping)</td>
</tr>
<tr>
<td>XML, JSON</td>
<td>Serialisation of this information for the purpose of technical communication between phases.</td>
</tr>
<tr>
<td>RDF</td>
<td>Mapping of this information to enable full use of the advantages of semantic technologies.</td>
</tr>
</tbody>
</table>

Figure 32 Graphic View on Exchange Data Formats for the Asset Administration Shell

The specifications of the preceding clause are now specifically transferred to the individual data exchange formats.

4.2 General Rules

7The abbreviated use of the word “data formats” includes the use of conceptual advantages such as information models, schemes, transmission protocols, etc.

8 Only data formats considered in this document so far are mentioned in the figure.
In the following we distinguish between global and model keys. They are defined as follows:

- A **global key** is a key with idType <> IdShort. A global key can be local (local = true) if it references an element within the same AAS, for example a ConceptDescription or another Submodel.

- A **model key** is a key with type <> GlobalReference, i.e. it references a model element within the same AAS (local = true) or within another AAS (local=false).

- A similar distinction is done for references:
  - A **model reference** is a reference key chain in which the last key is a model key.
  - A **global reference** is a reference key chain in which the last key is a global key with type = GlobalReference.
  - An **external global reference** is a global reference for which the first key in the reference key chain is not local (local = false).
  - A **local global reference** is a global reference for which the first key in the reference key chain is local (local = true).

The following rules hold and ensure that potential cyclical References can be serialized:

- In a Reference key chain, a key with local “true” is followed either by no key or a key with "local" is "true".
- In a Reference key chain, a key with local “false” is followed either by no key or a key with "local" is "true"

### 4.3 Unified example

The following example is used to demonstrate the main features of the data formats as explained in the following clauses for different data formats. Intention is to motivate the equivalency of information in different representations. The examples themselves can be found in the annex.

It shows an AAS with two properties: the actual rotation speed (idShort = “rotationSpeed”), a measurement value (category=VARIABLE) as well as the maximum rotation speed “NMax” (category=PARAMETER). The AAS represents a controller with short id “3S7PLFDRS35”.

Up to now there is no property defined within eCl@ss for the actual rotation speed. Therefore a corresponding concept description (with idShort=“N”) is added to the local dictionary of the AAS. It gets the global identifier “id=www.festo.com/dic/08111234” that is referenced via semanticId in the property “rotationSpeed”.

For the maximum rotation speed eCl@ss provides a semantic definition with global identifier “0173-1#02-BAA120#007”. A copy of the entry is created within the local dictionary. The id of the copy is the same as in eCl@ss.

The physical unit of the rotation speed properties and concept description is 1/min, denoted by a globally unique IRDI “0173-1#05-AAA650#002” for 1/min as defined by eCl@ss.
Figure 33 Example rotation speed for serialization to data formats
4.4 XML

4.4.1 General

In the following clauses an overview of the main concepts of the AssetAdministration Shell XML serialization is presented. For import and export scenarios the metamodel of an AssetAdministration Shell needs to be serialized. A serialization format is XML. The information is divided in three parts. The first part discusses the rules, in the second part are examples for some specific rules and in the third part the schema and a complete example is shown in the annex.

4.4.2 Introduction

eXtensible Markup Language (XML) is very well suited to deriving information from an IT system, perhaps to process it manually, and then to feed it into another IT system. It therefore meets the needs of the information sharing scenario defined in Section 0. XML provides for the possibilities of scheme definitions which can be used to syntactically validate the represented information in each step. For this reason, this document provides basic scheme definitions to permit a validation of information which is shared.

The XML definitions are divided into two different files:

- IEC61360 datatype definition: iec61360.xsd
- Core definitions for the AssetAdministration Shell and its export container: aas.xsd

Subsequently, an example in XML is provided.

4.4.3 Rules

The main concepts of the XML schema and the resulting XML serialization are explained by the following rules. Rules 1 through 6 are general rules, while rules 7 through 11 are specific to References.

1. **XSD global Types are used for modeling**
   For reusability XSD global types will be used for modeling. There will be a naming convention `<informationModelName>_t`

2. **If present, names are taken from the information model.**
   For comprehensibility reasons the XML key names should be the same as the representing Element in the metamodel.

3. **All identifiables have an aggregation on root level.**
   The identifiables are AssetAdministrationShells, Assets, Submodels, ConceptDescriptions. To reduce redundancy instances, they are located exclusively in the top-level aggregation.

4. **Repeating elements and their types will get the same names of their instances in plural.**
   If the element has a cardinality of n>1 a parent element will be used with the name of the name of the element in plural. For example, each element in the aggregation `assets` needs to be an `asset`.

5. **Identifiables which are not in the top-level aggregations are only references to the corresponding instances in one of the top-level aggregations.**
   This rule completes the concept of rule 3. There should be no redundant identifiable in the serialized metamodel.

6. **For elements with type langString an aggregation element is added. For the single element a language tag “lang” is added.**
   For internationalization purposes this rule is necessary.

7. **The attributes of a key in a reference except for the value itself are realized as XML attributes.**

8. **Data Specification Templates are directly added to the Concept Description because up to now only property descriptions are supported.**

9 see: https://de.wikipedia.org/wiki/Extensible_Markup_Language
Additionally, a new element EmbeddedDataSpecification is introduced that has two attributes: one for the global reference to the data specification identifier and one for the content of the data specification.

### 4.4.4 Example for top-level structures

One serialization describes one asset Administration Shell environment that is a collection of Administration Shells. The root element of the AssetAdministration Shell environment has 4 aggregations. For each identifiable class, one aggregation is featured, as required by rule 3.

The resulting XML is the minimal XML:

#### Table 7 Minimal XML for top level structure

```xml
<?xml version="1.0" encoding="UTF-8"?>
  <aas:assetAdministrationShells>
    </aas:assetAdministrationShells>
</aas:aasenv>
```

Note: `<` designates line-wrap for purpose of layout
4.4.5 XSD Model Groups

There are a number of attribute groups in the UML model – i.e. identifiable or hasSemantics. These groups are modelled as XSD model groups so they could be reused as anonymous groups in different places.

Figure 35 XSD Model Groups

This is realized in the according XSD as follows:

Table 8 Using XSD Model Groups

```
<complexType name="assetAdministrationShell_t">
  <sequence>
    <group ref="aas:identifiable"></group>
    <group ref="aas:hasDataSpecification"></group>
    <element name="derivedFrom" type="aas:reference_t"/>
    <element name="assetRef" type="aas:reference_t"/>
    <element name="submodelRefs" type="aas:submodelsRef_t"/>
    <element name="views" type="aas:viewsRef_t"/>
    <element name="conceptDictionaries" type="aas:conceptDictionaries_t"/>
  </sequence>
</complexType>
```

Note: due to XSD group mechanism, hasDataSpecification maps to an element of embeddedDataSpecification_t and identifiable maps to multiple elements in Figure 35.
4.4.6 Keys and References

Keys and References (see 3.5.13) are mapped on the same XML schema construct. Some of the attributes have enumerations defined – these are mapped on string constraints.

Figure 36 Keys and References

4.4.7 Asset Administration Shell Mapping

Asset Administration Shells are mapped using the following XML Schema construct – it consists of a set of meta data parameters and mostly links to other parts of the XML document or to external entities (based on keys and references).
4.4.8 ConceptDescriptions and EmbeddedDataSpecifications Mapping

As described above, the definition of a concept comprises of an according reference and a content, which is realized by a data specification.

Note: EmbeddedDataSpecification was named "ConceptDefinition" in a former version of the metamodel. The figures are not yet updated.

Figure 38 Concept description in XML in general
The data specification can be e.g. along of an IEC 61360 property:

**Figure 39 Data specification via IEC 61360 property attributes**

Full XSD and example XML can be found in Annex D.
4.5 JSON

4.5.1 General

In the following clauses an overview of the main concepts of the AssetAdministration Shell JSON serialization is presented. For import and export scenarios the metamodel of an AssetAdministration Shell needs to be serialized. A serialization format is JSON\textsuperscript{10} (JavaScript Object Notation). The information is divided in three parts. The first part discusses the rules, in the second part are examples for some specific rules and in the third part the schema and a complete example is shown in the annex.

The publicly funded project BaSys 4.0 provides an open source implementation of the Asset Administration Shell and its JSON serialization by the end of 2018.\textsuperscript{11}

4.5.2 Rules

The main concepts of the JSON serialization are explained by the following 11 rules. Rules 1 through 6 are general rules, while rules 7 through 11 are specific to References.

1. If present, names are taken from the information model.
   For comprehensibility reasons the JSON key names should be the same as the representing Element in the metamodel.

2. Each object has an additional attribute “modelType” with the name of the corresponding object class as value
   This rule is needed for deserialization reasons.

3. All identifiables have an aggregation on root level.
   The identifiables are AssetAdministrationShells, Assets, Submodels and ConceptDescriptions. To reduce redundancy instances, they are located exclusively in the top-level aggregation.

4. Aggregation Names are the names of their instances in plural.
   If the value of a key value pair is a JSON array the key name needs to be the name of the instances in this JSON array in plural. For example, each object in the aggregation assets needs to be an asset.

5. Identifiables which are not in the top-level aggregations are only references to the corresponding instances in one of the top-level aggregations.
   This rule completes the concept of rule 3. There should be no redundant identifiable in the serialized metamodel.

6. The (multi-language) Description in the metamodel is always an aggregation of descriptions in the serialized JSON.
   For internationalization purposes this rule is necessary.

7. All ordered Collections including Keys have an index. The first object in the Collection has the index 0.
   Because the Reference key chain is an ordered list the index attribute is needed.

8. Data Specification Templates are directly added to the Concept Description because up to now only property descriptions are supported.
   Additionally, a new element EmbeddedDataSpecification is introduced that has two attributes: one for the global reference to the data specification identifier and one for the content of the data specification.

4.5.3 Example for top-level structures

One serialization describes one asset Administration Shell environment, that is, a collection of Administration Shells. The root element of the AssetAdministration Shell environment has 4 aggregations. For each identifiable class, one aggregation is features, as required by rule 3.

\textsuperscript{11} BaSys 4.0 SDK open source implementation see: https://projects.eclipse.org/projects/technology.basyx
Figure 40 Top level structure of an AssetAdministration Shell environment mapped to JSON

![Diagram showing top level structure](source: Plattform Industrie 4.0)

The resulting JSON is the minimal valid JSON:

Table 9 Minimal JSON for top level structure

```json
{
    "assetAdministrationShells": [],
    "assets": [],
    "submodels": [],
    "conceptDescriptions": []
}
```

4.5.4 Examples for References to Identifiables

As required by rule 5, Identifiables are only allowed to be located in the top-level aggregations. In deeper parts of the structure only References to the corresponding Identifiable take place.

In the AssetAdministration Shell AAS1, the submodel S1 is only a Reference to the Submodel S1 instance in the top level Submodels aggregation.

Figure 41 Submodel reference in AssetAdministrationShell for JSON

![Diagram showing submodel reference](source: Plattform Industrie 4.0)
This results in the following exemplary JSON:

Table 10 Exemplary minimal JSON for References

```json
{
    "assetAdministrationShells": [
        {
            "modelType": "AssetAdministrationShell",
            "submodels": [
                {
                    "keys": [
                        {
                            "keyType": "URI",
                            "local": true,
                            "type": "Submodel",
                            "value": "http://env.com/submodels/S1",
                            "index": 0
                        }
                    ],
                    "assets": []
                }
            ],
            "assets": []
        }
    ],
    "assets": []
}
```

4.5.5 Examples for Descriptions

As described in rule 6, a description in the serialization is an array of descriptions from the metamodel.

Table 11 Exemplary minimal JSON for top level structure

```json
"descriptions": [
    {
        "text": "Beispiel Beschreibung",
        "language": "DE"
    },
    {
        "text": "Sample Description",
        "language": "EN"
    }
]
```

4.5.6 Examples for ReferenceElement

A ReferenceElement has a Reference as value. This Reference has an aggregation of keys which represents a key chain. The resolved key chain points to an element. In this example the ReferenceElement’s value points to a property of another submodel in another Asset Administration Shell environment. The first key is a global key with “local”-attribute set to false, i.e. the reference is not part of the own environment. The second key is a model key which is used to define the corresponding property in the other environment by its IdShort. It is best practice to use the shortest key chain if there are multiple options.
This results in an exemplary JSON as such:

```json
{
  "keys": [
    {
      "keyType": "URI",
      "local": false,
      "type": "Submodel",
      "value": "http://admin-shell.io/submodels/Temperature",
      "index": 0
    },
    {
      "keyType": "IdShort",
      "local": true,
      "type": "Property",
      "value": "NMax",
      "index": 1
    }
  ]
}
```

Table 12 Exemplary ReferenceElement in JSON
4.5.7 Examples for GlobalReference

Sometimes it is useful to refer to another standard or something that is not provided by the own AssetAdministration Shell environment. In this example the semantics of a Property refers to eCl@ss.

**Figure 43 Usage of GlobalReference in JSON**

This results in an exemplary JSON as such:

**Table 13 Exemplary GlobalReference in JSON**

```json
{
   "keys": [
      {
         "keyType": "IRDI",
         "local": false,
         "type": "GlobalReference",
         "value": "0173-1#02-AAC962#006",
         "index": 0
      }
   ]
}
```
4.5.8 Example for a kind = "type" Reference

A semantic description can either be something external or an instance with kind = "type". In this example the Property P2 uses P1 as a template. P1 has kind = "type" and P2 kind = "instance".

Note: typically, types are assumed to be specified in another Asset Administration Shell as the instances. Here, the depicted situation is simplified for layout reasons.

Figure 44 Exemplary type Reference in JSON

This results in an exemplary JSON as such:

Table 14 Exemplary type Reference in JSON

```json
{
  "keys": [
    {
      "keyType": "URI",
      "local": true,
      "type": "Submodel",
      "value": "http://aasenv1.com/submodel/S1",
      "index": 0
    },
    {
      "keyType": "IdShort",
      "local": true,
      "type": "Property",
      "value": "P1",
      "index": 1
    }
  ]
}
```
4.6 RDF

As of November 2018, the mapping towards RDF is under discussion. The results will be made available as soon as they are finalized.

4.7 OPC UA

The works of the mapping to the OPC Unified Architecture are currently carried out in a joint working group between OPC Foundation, ZVEI and VDMA. The results will be made available as soon as they are finalized.

4.8 AutomationML

As of November 2018, the mapping towards AutomationML are currently work in progress. The results will be made available as soon as they are finalized.

12 see: https://opcfoundation.org/collaboration/i4aas/
5 Attribute Based & Role Based Access
5.1 Passing Permissions for Access

When having a look at the leading picture (Figure 1 in clause 2.2) also security aspects have to be considered when transferring information from one value chain partner to the next.

When admin shell content is passed from one partner to the next, the following steps need to be done, here shown for the example that the supplier passes on content to the integrator:

- **Step A1-A2**: The supplier makes a choice which data is to be passed on (see clause 5.2), and thus determines the content of the AASX package (see clause 6).
- **Step A2-A3**: The AASX package is transferred to the integrator.
- **Step A3-A4**: The integrator receives the package and imports the content into his security domain. During this step, the integrator has to establish access rights according to the requirements in his own security domain.

This demonstrates that access rights are independent between the two security domains.

The admin shell uses attribute based access control (ABAC), a role can be considered as one attribute in this context; other attributes might be time-of-day, originating address and others.

Two boundary conditions require the passing on of access permissions between partners:

(a) Access permissions to information elements of an AAS must be established in each security domain.

(b) One partner must be able to pass a suggestion which access permissions should be established for the asset that is described in the AAS.

An example for the second requirement: a robot manufacturer suggests that for the robot the following roles should be established: machine setter, operator and a maintenance role. He also suggests permissions for these roles, e.g. an installer does have write-access to the program of the robot, but an operator does not.

The above example motivates, that the semantics of access permission rules and their exact definitions need to be passed from one security domain to the other.

The passing on of the semantics of attribute based access is implemented by following means:

- **Definition of access permissions**: The detailed access permission (e.g. read, write, delete, create, invoke method etc.) are defined in a domain specific submodel (see *defaultPermissions* and *selectablePermissions* in clause 5.4.5).
- **Definition of the access permission rules**, based on the defined access permissions. These are defined as part of access control (see clause 5.4.6).
- **Association of access permission rules** to each information element (object) of the AAS. This means is realized by the information structure of the AAS, itself (see *PermissionsPerObject* in clause 5.4.6).

In [19] examples and more background information on attribute access control and access control in general can be found.

5.1.1 Effective Access based on Access Permission Rules

Effective access permissions are determined based on the access permission rules.

Each information element (object) in the AAS shall have rules that defines its access permissions for each subject. The subject is assumed to be already authenticated.

If an information element does not have these rules, it will automatically use the table for the element where it is included (“inheritance from above”). The most upper object is the AAS itself, i.e. the AAS is the starting point for the inheritance.

As indicated before, subject identification, rule definitions and also permissions could be different for the receiving security domain.

When the receiving party establishes access permissions during step A3-A4, it must establish the passed-on access definitions (permissions and access permission rules) to the existing definitions in its security domain.
It also has to map the received access permission rule per info element to existing permission mechanisms in its security domain.

5.2 Filtering of Information in Export and Import

When exchanging information from partner A to partner B there are two use cases:

- The producer of information does not want to submit the complete information but only parts of it. The information submitted might vary depending on the specific consumer the information is submitted to. I.e. a filtering mechanism is needed that allows to individually shape the information for the specific consumer.
- The consumer of information does not want to include all information provided by the producer of information in his own process, i.e. he wants to filter only the relevant information.

Figure 45 Example Filtering for Export and Import

As an example, assume that the producer is submitting the complete order data. However, the consumer (in this case the machine builders) is filtering the information (1) and is only importing the information relevant to him. For the functionality both are filtering: the producer is filtering what he submits to the consumer (2) and the consumer again is not using all functionality but is filtering again which functionality shall be used in his environment. The same is possible between machine builders and operator.

Table 15 shows an example when using the defined xml format as defined in this document. In the example the German translation shall not be submitted, only English language is provided for partner B.
Table 15 Example Filtering of Information in XML

```
[...]
<property>
  <idShort>NMax</idShort>
  <category>PARAMETER</category>
  <description lang="EN">maximum rotation speed</description>
  <description lang="DE">maximale Drehzahl</description>
  <ref hasSemantics>
    <keys>
      <key local="false" type="GlobalReference" keytype="RID">0173-1#02-baa120#007</key>
    </keys>
  </ref>
  <value>2000</value>
</property>
[...]
```

Only Lang = “EN”

5.3 Overview Metamodel Asset Administration Shell for Security

The security attributes are a mandatory part of any Administration Shell.

The security attributes describe:

- Access Control Policy Points including definition of access permission rules
- Trust anchors

In this document mainly the aspect of access permission is dealt with. The underlying concept is the concept of attribute based access control (ABAC) as described in [22].
The overall concept is depicted in Figure 46: A subject is requesting access to an object (1). In the context of an AAS an object typically is a submodel or a property or any other submodel element connected to the asset. The implemented access control mechanism of the AAS evaluates the access permission rules (2a) that include constraints that need to be fulfilled w.r.t. the subject attributes (2b), the object attributes (2c) and the environment conditions (2d).

In Figure 47 an overview of the information model of the AAS w.r.t. security is given. The focus is on access control.

An object in the context of ABAC corresponds typically to a submodel or to a submodel element. The object attributes again are modelled as submodel elements.

Subject Attributes need to be accessed either via an external policy information point or they are defined as properties within a special submodel of the AAS. A typical subject attribute is its role. The role is the only subject attribute defined in case of role based access control.

Optionally, environment conditions can be defined. In role based access control no environment conditions are defined. Environment conditions can be expressed via formula constraints. To be able to do so the values needed should be defined as property or reference to data within a submodel of the AAS.
Via access permission rules it is defined which subject is allowed to access which objects within the AAS. It is assumed that the subject is already authenticated. Objects can be any referable elements, i.e. they include submodels, assets, concept descriptions, views etc. More general it can be specified whether an authenticated subject is allowed or denied to access an object a.s.o. “Access” might be one of the specified permissions on an element of the AAS. Which permissions are selectable is not defined by the metamodel of the AAS. The selectable permissions are defined via a submodel \( \text{selectablePermissions} \). The default subject attributes and default permissions are used if they are not overwritten by the owner of the AAS.

As for permissions the used authenticated subject attributes are defined in submodel \( \text{selectableSubjectAttributes} \). The same holds for the subject attributes \( \text{selectableSubjectAttributes} \).

Via formula constraints the access rights might be further constrained. For example a formula might specify that the role “maintenance engineer” (to be more precise: an authenticated subject with subject attribute “role = ‘maintenance engineer’”) is only allowed to write configuration parameters if the machine (the asset) is not running. See Figure 15 in clause 3.5.2.6 for a formal expression of this access rule based on the property “Status”.

Object Attributes are handled in a different way. It is assumed that any property of the object in focus can additionally take over the role of an object attribute. Therefore there is no special submodel for default or selectable object attributes.

Also the more traditional role based access control can be realized for an AAS: in this case there are no constraints (= environment attributes) defined for the access control rules. For a subject only one subject attribute needs to be defined: its role. For the object no additional object attributes need to be defined.

13 The term “object” is used because it is more generic and in future also other objects like for example attributes of classes may be included besides elements.
For more details on attribute based access control including examples how to apply the metamodel as defined in this document see [19].

The classes and their attributes are defined in the following clause 5.4.

Figure 48 gives an overview of all elements defined for security issues in the metamodel.

**Figure 48 Security Overview Packages**

---

### 5.4 Metamodel Specification Details: Designators

#### 5.4.1 Introduction

In this clause the classes of the metamodel related to security are specified in detail. It is an extension of the metamodel as described in clause 3.5.

For understanding the extension the basics and common abstract classes need to be understood (see especially clause 3.5.2, clause 3.5.13 and clause 3.5.14).

#### 5.4.2 Common

*Endpoint* is not yet specified in detail in the current metamodel. It is just an abstract class.
5.4.3 Security Attributes

Figure 49 Metamodel for Security Attributes of AAS

<table>
<thead>
<tr>
<th>Class:</th>
<th>Security</th>
</tr>
</thead>
<tbody>
<tr>
<td>Explanation:</td>
<td>Container for security relevant information of the AAS.</td>
</tr>
<tr>
<td>Inherits from:</td>
<td></td>
</tr>
</tbody>
</table>

<table>
<thead>
<tr>
<th>Attribute (*=mandatory)</th>
<th>Explanation</th>
<th>Type</th>
<th>Kind</th>
<th>Card.</th>
</tr>
</thead>
<tbody>
<tr>
<td>accessControlPolicyPoints*</td>
<td>Access control policy points of the AAS.</td>
<td>AccessControlPolicyPoints</td>
<td>aggr</td>
<td>1</td>
</tr>
<tr>
<td>trustAnchor</td>
<td>Trust anchor of AAS, typically certificates.</td>
<td>Certificate</td>
<td>aggr</td>
<td>0..*</td>
</tr>
</tbody>
</table>

In general it has to be considered how to enable the first configuration of the AAS w.r.t. security. This would include setting the authorization provider endpoint etc.

There is not only one trust anchor per AAS because certificates can be overwritten if an AAS is taken over by a new owner. The new owner adds a new certificate. Nevertheless the complete set of certificates needs to be available.

Certificate is not yet further defined.

5.4.4 Access Control Policy Point Attributes

Figure 50 Metamodel for Access Control

<td></td>
</tr>
<tr>
<td>policyInformationPoints: PolicyInformationPoints [0..1]</td>
<td></td>
</tr>
</tbody>
</table>
The definition of policy decision point (PDP) is taken from [22]. The PIP computes access decisions by evaluating the applicable decision points and meta policies. One of the main functions of the policy decision point is to mediate or deconflict decision policies according to meta policies. Either the decision taking is done within the AAS. Then, the AAS is autonomous and independent from an external access control system. Or the decision taking is done outside the AAS. Then, the AAS needs to be able to access this external endpoint for decision taking.
The definition of policy information point (PIP) is taken from [22]. The difference between external and internal information points is whether the AAS needs access via an endpoint to an external source of information or whether the AAS stores the needed information itself. There might also be external and internal information points for an AAS to be considered for decision taking.

### 5.4.5 Local Access Control Attributes

6 Package File Format for the Asset Administration Shell (AASX)
6.1 General

In some use cases it is necessary to exchange the full or partial structure of the Asset Administration Shell with or without associated values and/or make the information persistent (e.g. store it in a file server). This would mean that it is necessary to define a file format that can hold and store this information. Therefore, a package file format for the Asset Administration Shell (AASX) is defined based on the following requirements:

- Generic package file format to include the Asset Administration Shell structure, data and other related files
- Main use cases are the exchange between organizations/partners and storage/persistency of the Asset Administration Shells’ information.
- Without any legal restriction and no royalties. Preferably based on an international standard with high guarantees of future maintainability of that format
- Existence of APIs to create, read and write this format
- Digital signatures & encryption capabilities must be provided
- Policies for authenticity and integration of package files

6.2 Selection of the reference format for the Asset Administration Shell package format

The ZVEI Führungskreis Industrie 4.0 – Spiegelgremium Modelle & Standards has decided to use the Open Packaging Conventions (OPC)\textsuperscript{15} format as the reference for the Asset Administration Shell package format definition, due to the following reasons:

- Open Packaging Conventions is based on ZIP (as a package container) and XML (for the description of some internal files and definitions). Those two technologies are the most widely used in their respective domains and are also addressed for long-term archiving.
- Open Packaging Conventions can be used as package for non-office applications too (there are many examples available, such as NuGet, FDI packages, etc.). It provides a logical model that is independent from how the files are stored in the package. This logical model can be expanded to any sort of application.
- Open Packaging Conventions is also used in the scope of Industry (e.g. FDI packages, MTP – Namur Modul Type Package) and currently in discussion as possible container format for some FDT® and ODVA Project xDS™ use cases.
- Open Packaging Conventions (and Open Document Format packages too) supports digital signing. It can be done for individual files inside the package. Encryption isn’t specified in Open Packaging Conventions (it only mentions what shall not be done). Anyway, encryption is still possible (see later)
- There are some APIs to handle Open Packaging Conventions packages (Windows API, .NET, Java, …) without the need of much knowledge on the technical specification
- Chunking in Open Packaging Conventions is encouraged, i.e. split files into small chunks. This is better for reducing the effect of file corruption and better for data access.
- There are some international organizations that recommend using Open Document Format (ISO/IEC 26300-3) instead (e.g. EU, NATO, …), but this recommendation is related to the formats used specifically in office applications.
- The Office Open XML and Open Packaging Conventions specifications originated from Microsoft Corporation and later standardized as ISO/IEC 29500 and ECMA-376. Current and future versions of ISO/IEC 29500 and ECMA-376 are covered by Microsoft’s Open Specification Promise, whereby Microsoft “irrevocably promises”

\textsuperscript{14} Role-based policies to access this package is not defined, as this is a feature of the systems that host the AASs (see section 0)

\textsuperscript{15} Not to be confused with OPC (Open Platform Communication) of the OPC Foundation. Therefore, we will use the full term of “Open Packaging Conventions” instead of the abbreviation “OPC”.
not to assert any claims against those making, using, and selling conforming implementations of any specification covered by the promise (so long as those accepting the promise refrain from suing Microsoft for patent infringement in relation to Microsoft's implementation of the covered specification). [24]

- Office Open XML (including the Open Packaging Conventions format) and Open Document Format are politically conflicting formats (see details in [25] and [26]). Choosing Open Packaging Conventions as the option for storing the Asset Administration Shell information was solely a technical decision based on the arguments mentioned here.
- Open Packaging Conventions was chosen in favour of iiRDS (v1.0). The scope of iiRDS might not be aligned with the requirements of the Asset Administration Shell, i.e. iiRDS is mostly a format for storing technical documentation of industry devices based on concepts of ontology.

6.3 Basic concepts of the Open Packaging Conventions

The packaging model specified by the Open Packaging Conventions describes packages, parts, and relationships. Packages hold parts, which hold content and resources, such as files\(^{16}\). Every file in a package has a unique URI-compliant file name along with a specified content-type expressed in the form of a MIME media type.

Relationships are defined to connect the package to files, and to connect various files in the package. The definition of the relationships is the logical model of the package. The resource that is a source of a relationship must be either the package itself or a data component (file) inside of the package. The target resource of a relationship can be any URI-addressable resource inside or outside of the package. It is possible to have more than one relationship that share the same target file (see example 9–6 in ISO/IEC 29500-2: 2012).

The physical model maps those logical concepts to a physical format. The result of this mapping is a physical package format (a ZIP archive format) in which files appear in a directory-like hierarchy. Any individual or organization can design a physical package format by mapping logical package concepts to a desired physical format. Thus, package format designers can design and optimize a physical format for the specific needs of an application without compromising the logical structure of the package (adapted from [27] and [28]).

6.4 Conventions for the Asset Administration Shell package file format (AASX)

The Asset Administration Shell Package (AASX) format derives from the Open Package Conventions standards, consequently inheriting its characteristics. Nevertheless, some convention shall be defined for the AASX:

- Package format and rules according to ISO/IEC 29500-2:2012. Any derivate format from this standard (such as the AASX format) requires the definition of a logical model, physical model and a security model. Those specific conventions are described in the next subsections.
- File extension for the AASX format: .aasx
- MIME-type for the AASX format: application/asset-administration-shell-package\(^{17}\)
- Icon for the AASX (to be defined).
- The AASX format can be identified by the file extension and MIME type. Content-wise, it is possible to identify it when reading the first relationship file /_rels/.rels (as defined in Open Packaging Conventions) and looking for a relationship type http://www.admin-shell.io/aasx/relationships/aasx-origin (which is the entry point for the logical model of the Asset Administration Shell).
- The following paths and filenames in the package are already reserved by the Open Packaging Conventions specification and therefore shall not be used for any derivative format: /[Content_Types].xml

---

\(^{16}\) The term “file” will be used instead of “part”.

\(^{17}\) The currenty MIME-type is provisory and needs to be requested oficially.
6.5 Logical model

As mentioned before, it is necessary to define a logical model for formats on top of Open Packaging Conventions.

Figure 53 defines the logical model for the AASX format. It is made of a set of relationship types (URI), their cardinality (how many relationships of that type are possible) and the source of the relationship. In addition (not shown in Figure 53), a specific relationship instance has also a unique ID and a target resource (URI of a target file inside or outside the package).

Figure 53 Logical model for the AASX format

The relationships for thumbnail, core-properties, digital-signatures (origin, signature and certificate) are defined by Open Packaging Conventions, so no need to reinvent. The other relationships were specifically defined to support the Asset Administration Shell specific files. Here a short description on each relationship of Figure 53:

- **thumbnail** – Optional. Required to define a thumbnail for that package (e.g. picture of the administrated device). The thumbnail picture can be shown instead of the package’s icon based on the extension and/or MIME type.

- **core-properties** – Optional. There is a schema for describing the package through "core properties," which uses selected Dublin Core metadata elements in addition to some Open Packaging Conventions-specific elements. The core-properties do not describe the Administration Shell, but the package itself. Some elements of the core-properties may be similar/equal to elements of the Administration Shell. Some core-properties are: Title, Subject,
6.6 Physical model

The physical model defines how the different files are stored in the package, based on Open Packaging Conventions and how files are addressed in the relationships. As mentioned before, the physical package format is a ZIP file that can be open and edit in any PKWARE/ZIP compatible application.

In order to utilize the identifiers of Administration Shell and SubModels, **friendly names** are required. The friendly name of such entities is built by searching all characters of the identifier, which are not letters or digits and substituting them with an underscore "_".

A feature of this physical and logical model is that the filename and location of those files can be customized (if associated relationships have a correct URI to those files, and therefore can be used to locate the files according to the logical structure). For example, one package producer might store an aas-spec file in /aass/device.xml, the other one in /asset-admin-shell/productX123.xml, but both use the same relationship type for that files. To have a more consistent approach on the physical model, the following best-practice is defined for storing files inside the AASX package:

- Open Packaging Conventions related files should be stored according to the API that was used to generate/manipulate the AASX package (it is not recommended to do this manually).
- /aass/ shall be the root folder for the AASX package specific information.
- /aass/aass-origin shall be the target of the relationship aass-origin without content (empty file).
- /aass/<aas-friendly-name>/ shall be the folder for storing all files for a specific AAS, where <aas-friendly-name> is the friendly name of the AAS.
- /aass/<aas-friendly-name>/<aas-friendly-name>.aas.<extension> shall be the target of a relationship of type aas-spec, where <extension> is the extension based on the type of serialization (e.g. .xml, .json).
- /aass/<aas-friendly-name>/<aas-friendly-name>.<view-idshort>.view.<extension> shall be the target of a relationship of type aas-spec-split that contains a specific view definitions of an AAS. This is only required if the view definitions aren’t defined in the target file of aas-spec.
• `/aasx/<aas-friendly-name>/aas-friendly-name>.dic.<extension>` shall be the target of a relationship of type aas-spec-split that contains the ConceptDictionary definition of an AAS. This is only required if the ConceptDictionary isn’t defined in the target file of aas-spec.

• `/aasx/<aas-friendly-name>/aas-friendly-name>.secattrib.<extension>` shall be the target of a relationship of type aas-spec-split that contains the Security model of an AAS. This is only required if the Security models isn’t defined in the target file of aas-spec.

• `/aasx/<aas-friendly-name>/submodel-friendly-name/` shall be the folder to store files related to a submodel of an AAS (targets of aas-suppl relationships that are referenced in that submodel and splits containing submodel information). `<submodel-friendly-name>` is the friendly name of the submodel.

• `/aasx/<aas-friendly-name>/submodel-friendly-name/submodel-friendly-name>.submodel.<extension>` shall be the target of a relationship of type aas-spec-split that contains a submodel definition of an AAS. This is only required if a submodel isn’t defined in the target file of aas-spec.

Those file names must only contain characters that can be used for file names.

The conventions defined here shall not be used for other files. E.g. any other file in a submodel folder shall not contain the substring “.submodel.” in its name.

Note that the format of the files targeted by the relationships aas-spec and aas-spec-split depend on the serialization format that was used to generate them (e.g. xml, json, …).

It is also possible to have different serialization formats of the same Administration Shell stored in the same AASX. In this case, the different serialization formats can be stored in parallel with different extension, different MIME type and different relationships. For example, Waterpump24634.aas.xml and Waterpump24634.aas.json are stored in the same folder Waterpump24634, but are targets of different relationships (different IDs) of the same relationship type aas-spec. Both are then the entry-point of different source relationship branches (each one having its own .rels file, i.e. Waterpump24634.aas.xml.rels and Waterpump24634.aas.json.rels).

• To avoid duplication of data, it is possible to target the same file by different relationships (e.g. two different relationships of type aas-suppl may have the same target file).

An example of a physical model for an AASX based on a sample product is shown in Figure 54. It shows the content of the package listed in a tree view and one example mapping to the logical model as defined in Figure 53. The physical structure is based on the best practice mentioned before. Note that in the example there is only one AAS in the package, one submodel (programs) is stored in a separate file and the certificate is embedded into the signature file (so no need of the additional relationship). It is also assumed in this example that the AAS specification files are serialized into XML.
It is possible to classify the files in a AASX package into the following types: 1) files that are referenced in the relationships of the logical model and must match the target URI inside each relationship, 2) “Files that aren’t source or target of any relationship (not allowed as they do not follow the logical model defined in this document and might impact some aspects regarding digital signatures and its verification) and 3) Open Packaging Conventions specific files that aren’t associated to the logical model (relationships):

- **/Content_Types.xml** – contains a list of extensions and MIME type of all file types inside the package. The element override can specify the MIME type for specific files independent of the extension. The MIME type of AASd-specific files depends on the type of serialization that was used to generate the content of the files (e.g. if XML was used for some files, then the MIME type "text/xml" together with the used file extensions must appear in [Content_Types].xml. If there is no specific MIME type for some files, then "application/octet-stream" shall be used.

- **/_rels/.rels** – contains all relationships coming from the source “root” (which is the package itself), binding the source with a target (the URI of an internal file or external resource). For example, for the thumbnail relationship it looks like this:

  ```xml
  <Relationship Type = "http://schemas.openxmlformats.org/package/2006/relationships/metadata/thumbnail" Target = "http://www.admin-shell.io/aasx/relationships/aas-spec-split" Id = "9f6dd5ef656a8g0g"/>
  ```

  This means that the target data for this thumbnail relationship is stored in /Thumbnail.jpeg.

- **/<file_path>/_rels/<filename>.rels** – non-root relationships are stored in those files. E.g. the relationship based on type aas-spec-split starting from the source file Waterpump24634.aas.xml are stored in file /aasx/Waterpump24634/_rels/Waterpump24634.aas.xml.rels.

An AASX can be generated by using different means:

- Manually by adding files (changing files) to (of) a Zip file. This requires a deep understanding of the Open Packaging Conventions format, because adding just a file to the package with an ZIP editor isn’t enough (i.e. need to edit the [Content_Types].xml and some of the .rels files too)
Programmatically generating and changing the package format (e.g. using .NET System.IO.Packaging). This will typically avoid the errors that can be done when creating manually the package. In addition, the Open Packaging Conventions specific procedures, the logical, physical and security model defined for the derived AASX must be considered.

6.7 Digital signatures

Essentially the digital signature of an electronic document (in this case the files and relationships inside the container) aims to fulfil the following requirements [29]:

- that the recipient can verify the identity of the sender (authenticity);
- that the sender cannot deny that he signed a document (non-repudiation);
- that the recipient is unable to invent or modify a document signed by someone else (integrity).

A digital signature does not "lock" a document or cause it to become encrypted (although it may already be encrypted). Document content remains unchanged after being signed. Digital signatures do not prevent signed content from being viewed by unintended consumers.

A digital signing feature is already provided by the Open Packaging Conventions specification [27]. This signing framework for packages uses the XML Digital Signature Standard, as defined in the W3C Recommendation XML-Signature Syntax and Processing. This recommendation specifies the XML syntax and processing rules for producing and storing digital signatures.

- The package files defined for the signing framework are the origin file, the signature file(s), and the certificate file(s).
- digital-signature/origin file – starting point for navigating through the signatures in a package. The origin file is targeted from the package root using the digital signature origin relationship (as shown in the logical model in Figure 53). Multiple signature files may be targeted from the origin file. If there are no signatures in the package, the origin file will not be present.
- digital-signature/signature file(s) – contain markup defined in the W3C Digital Signature standard as well as in the packaging namespace. The files are targeted from the origin file with the signature relationship (as shown in the logical model in Figure 53).
- digital-signature/certificate file(s) – The X.509 certificate required for identifying the signer, if placed in the package, may be embedded within a signature file, or stored in a separate certificate file. The optional certificate file is targeted from a signature file with the certificate relationship. The certificate file can be shared between multiple signature files.

In the package, individual files and relationships can be independently signed, meaning that it is possible to select which files and relationships need a signature and which certificate to be used to sign. When the relationships file (.rels) is signed as a whole, all the relationships defined in that file are signed too. Moreover, it is possible to use more than one certificate to sign files and relationships.

The Open Packaging Conventions signing framework is quite flexible, and consequently some considerations must be taken, especially when defining policies. The Open Packaging Conventions specification does not define policies, only mentions that “designers that include digital signatures should define signature policies that are meaningful to their users”. Besides guaranteeing authenticity, non-repudiation and integrity, digital signatures shall also be used to define policies that are intended by the signers (typically the package producers) or in agreement with the package consumers (e.g. consumer will only accept package with signed content). The decisions taken during the signature process impact which consequent operations can be verified (e.g. allowing post-modification of a file, adding new relationships…).

---

20 Individual files and relationships can be signed, but not the full package. This is a question of definition, but signing the full package could mean to sign all files inside the package (except the signature file).

21 The policies described here are for the AASX package and what can be changed. It does not define any policy e.g. on how to use an AAS.
There is no need of a separate file in the package about policies, because these policies information can be retrieved on how signing is performed. Signing a specific file in the package will implicitly express the intention of the signer on what is or isn’t allowed with that file and related files (in case of relationship files). For instance, signing the aasx-origin relationship file will not permit adding new AAS to the package. If new AAS are added anyway, this will invalidate the original signature and nobody can blame the original signer for that change.

A package producer shall follow a digital signing policy based on the following options:

1. Sign nothing
2. Sign everything and thus following policy “No change allowed to the package” of Table 16.
3. Custom signing according to one or more policies of Table 16.

The package consumer may follow a validation process based on the policy of the signer(s) or an internal verification of the package according to its own policies. The signature policy defined by the signer(s) does not directly tell that the consumer should validate the package, but tells how it is intended by the signer(s). Nevertheless, validation might be mandatory for joint applications where several parties (package producers and consumers) need to follow the same rules. The following process for validation\(^{22}\) for AASX packages is established:

1. The validation process must start by checking that the consumed package is according to the Open Packaging Conventions specification and that it implements the logical model according to the AASX definition. Optionally it may analyse if the physical model is according to the best-practice for storing files inside the AASX package.
2. Files that aren’t source or target of any relationship, aren’t allowed (besides the Open Packaging Conventions specific files).
3. After these steps, the existing certificates that were used to sign the content of the package must valid and trusted.
4. All signed content must then be verified and valid against the provided certificate information.
5. The signed content will also reveal a set of policies\(^{23}\) defined by the signers or defined in agreement with the several parties (package producers and consumers), that must be followed by the consumer when changing the package without invalidating it (see Table 16).
6. A package is only valid, if all previous steps are performed successfully. Any change done to the package by the consumer requires a revalidation of the package.

Any of the steps mentioned in the validation can be performed independently without the other ones, but doing so, it is not considered as validation (e.g. internal verification process by a consumer may only require to check if the package is according to the Open Packaging Conventions and implementing the AASX logical model, without checking the signatures).

### Table 16 Set of possible policies based on how package files are signed, how to enable a given policy and the consequences of a policy

<table>
<thead>
<tr>
<th>Policy</th>
<th>How to enable the policy</th>
<th>Consequence</th>
</tr>
</thead>
<tbody>
<tr>
<td>No change allowed to the package</td>
<td>Sign all files and relationships in the package (except for [Content_Types].xml(^{24}) and the signature file(s))</td>
<td>Invalidates any change in the signed files. New files that are added afterwards do not have a signature and aren’t mentioned in any relationship, thus invalidating those files.</td>
</tr>
</tbody>
</table>

\(^{22}\) Validation. The assurance that a product, service, or system meets the needs of the customer and other identified stakeholders. It often involves acceptance and suitability with external customers. Contrast with verification, which is often an internal process. (Adapted from The PMBOK guide, a standard adopted by IEEE, 4\(^{th}\) edition)

\(^{23}\) These policies are for the AASX package and not for the AAS itself.

\(^{24}\) When reading an AASX package, do not rely on the trustability of the file [Content_Types].xml, as it was not possible to sign this file.
<table>
<thead>
<tr>
<th>No change allowed to the content of file X or deletion of file X</th>
<th>Sign file X inside the package (e.g. AAS, a submodel file, any file, …)</th>
<th>Invalidates tampering the content or deletion of file X.</th>
</tr>
</thead>
<tbody>
<tr>
<td>No change allowed to a relationship X</td>
<td>Sign relationship X</td>
<td>Invalidates tampering or deletion of the relationship entry (i.e. the relationship type, id and target URI) in the corresponding relationship file. This will not invalidate the content of source and target files of a relationship, once tampered.</td>
</tr>
<tr>
<td>No change allowed to any relationships that have source file X</td>
<td>Sign relationship file X (X.rels)</td>
<td>Invalidates adding, changing or removing any relationship mentioned in that relationship file. This will also invalidate the addition of new files that would otherwise being target in that relationship file. For example, if there is no relationship for the thumbnail in the root relationship file before the signing of that file, a posterior addition of thumbnail relationship is then invalidated.</td>
</tr>
<tr>
<td>Enable digital signatures</td>
<td>The digital-signature/origin relationship must be signed (alternatively, sign the complete root relationship file that contains this relationship)</td>
<td>Will enable digital signatures (but does not specify the rules for signing, e.g. if new signatures can be added).</td>
</tr>
<tr>
<td>Enable core-properties</td>
<td>The metadata/core-properties relationship must be signed (alternatively, sign the complete root relationship file that contains this relationship)</td>
<td>Will enable the core-properties of the package.</td>
</tr>
<tr>
<td>Enable thumbnail</td>
<td>The metadata/thumbnail relationship must be signed (alternatively, sign the complete root relationship file that contains this relationship)</td>
<td>Will enable the thumbnail for the package.</td>
</tr>
<tr>
<td>Forbid counter-signatures (adding new signatures)</td>
<td>Sign the signature origin relationship file</td>
<td>Invalidates counter-signatures.</td>
</tr>
<tr>
<td>Forbid modifying existing file/relationship digests for signatures based on a certificate</td>
<td>Sign object inside the corresponding signature file that contains all the file/relationship digests</td>
<td>Invalidates any change in the digests and addition of new file digests.</td>
</tr>
<tr>
<td>Enable AASX specification</td>
<td>The aasx-origin relationship must be signed (alternatively, sign the complete root relationship file that contains this relationship).</td>
<td>Will enable the AASX specification on top of the Open Packaging Conventions.</td>
</tr>
<tr>
<td>Forbid adding a new AAS or removing an existing AAS</td>
<td>Sign the aasx-origin relationship file</td>
<td>Invalidates adding or removing AAS.</td>
</tr>
<tr>
<td>Forbid adding a new splittable parts or removing an existing one to/from an AAS</td>
<td>Sign the aas-spec relationship file</td>
<td>Invalidates adding or removing of splittable parts to/from an AAS.</td>
</tr>
<tr>
<td>Forbid adding a new supplementary file or removing an existing one to/from an AAS</td>
<td>Sign the aas-spec relationship file</td>
<td>Invalidates adding or removing of extra files to/from an AAS.</td>
</tr>
</tbody>
</table>

### 6.8 Encryption

The Open Packaging Conventions specification (ISO/IEC 29500-2:2012) mentions that “ZIP-based packages shall not include encryption as described in the ZIP specification. Package implementers shall enforce this restriction. [M3.9]”\(^{25}\). 

\(^{25}\) The reason for this might be related to the transparency requirement for the package format as well as license requirements of PKWARE. For the ISO/IEC 21320-1 (Document Container File: Core) there is the following statement: “Encryption of individual files and of the central directory is prohibited. Hence this profile of ZIP_PK is more transparent than its parent format.” [30]
However, an Open Packaging Conventions package may be encrypted with other means and some applications using this package format as the basis for a more specific format, may use encryption during interchange or DRM for distribution. [24]

An example is the Office Document Cryptography Structure (MS-OFFCRYPTO) used by derivate office formats. Some used technologies may be covered by Patents from Microsoft and therefore it isn’t recommended for the AASX format. Digital Rights Management (DRM) can also be used to encrypt content elements in a package with specific access rights granted to authorize users (see the implementation in the system.io.packaging namespace [31]).

Regarding encryption and confidentiality, the following rules shall be followed:

1. Decide if there is a need of including confidential content in a package. If there is no reason, then the confidential content should not be included.

2. If encryption is desired for a temporary communication act (e.g. e-mail exchange, …) or if a AASX needs to be stored somewhere so that it can be opened later by the same entity, then encryption methods can be used for that specific mean (e.g. use BitLocker when storing the AASX in Windows-based systems that support it, use S/MIME for exchanging encrypted e-mails between entities, etc.).

3. For all other use cases26 where encryption is required for some or all of the content of the AASX:
   • Encryption methods can be used for individual files in the AASX package, as soon as the “encrypted” version replaces the original file in the package, the MIME type of the encryption format is known, and the MIME type must be listed in the [Content-Type].xml. The relationships as defined in this document remain the same, whenever content is encrypted or not. Note that Open Packaging Conventions related files as well as relationship files shall not be encrypted, and digital signing must be performed after encryption. One example of an encryption standard is the Secure MIME (S/MIME), where the encrypted content should be stored in application/pkcs7-mime format as defined in RFC 5652 and use the file extension *.p7m.
   • Besides encrypting the content of the package (individual files) it is possible to encrypt the full package (e.g. also using Secure MIME and saving the encrypted package in application/pkcs7-mime file format). In this case, the signature of the content of the package must be done before the encryption.

---

26 A use case could be to encrypt a submodel and only provide the access to the unencrypted data after paying a fee.
7 Summary and Outlook
In this document an UML metamodel for the structural viewpoint of the Asset Administration Shell is defined. An XML schema as well as for JSON schema are derived from it.

Additionally, a data specification template for defining properties is provided.

The following aspects will be covered by upcoming versions of the structural metamodel:

- Specifics for composite Administration Shells
- Event-Logging and History (including security aspects)
- Additional security aspects that were not yet needed for the use case under consideration like
  - Authentication
  - Certificates
- Reset Policies
- Additional data specification templates for additional types of submodel elements
- Handling of capabilities, skills and how they are related to operation.
- Definition of a formal formula language for constraints
- Further serializations as for AutomationML and RDF
- Additional attributes for administrative information, e.g. "time stamp", "time created" and "operational responsibility" as defined in IEC 62832 etc.

An OPC UA serialization is worked on in the joint work group of OPC Foundation, VDMA and ZVEI “I4AAS”.

The meta model and concepts of the Asset Administration Shell described in this publication are, among others, implemented in the open source Software Development Kit (SDK) of the publicly funded project BaSys 4.0. It comprises modules for creation, modification and export (XML and JSON) of Asset Administration Shells as well as others. It will be made available by the beginning of 2019\(^27\).

The next parts of the document series will cover:

- Interfaces and API for using a single AAS information model described in Part 1 (access, modify, query and execute information and active functionality)
- The infrastructure, which hosts and interconnects multiple AAS together. It implements registry, discovery services, endpoint handling and more.

\(^27\) [https://projects.eclipse.org/projects/technology.basyx](https://projects.eclipse.org/projects/technology.basyx)
Annex
Annex A. Concepts of the Administration Shell

1. General

In this clause, a general information is given about sources of information and relevant concepts for the Asset Administration Shell. Some of these concepts are explained in a general manner. Some concepts are update in order to reflect actual design decisions. No new concepts are introduced. Thus, the clause can be taken as a fully informative (annex) to the specification of the Administration Shell.

2. Relevant sources and documents

The following documents were used to identify requirements and concepts for the Administration Shell:

- Implementation strategy of Plattform Industrie 4.0 [1,2]
- Aspects of the research roadmap in application scenarios [7]
- Continuation of the application scenarios [8]
- Structure of the Administration Shell [4, 18]
- Examples for the Administration Shell of the Industrie 4.0 Components [6]
- Technical Overview “Secure identities” [9]
- Security of the Administration Shell [14]
- Relationships between I4.0 components – Composite components and smart production [12]

Note: The global Industrie 4.0 glossary can be found at: https://www.plattform-i40.de/I40/Navigation/EN/Service/Glossary/glossary.html
Note: The online library of the Plattform Industrie 4.0 can be found at: https://www.plattform-i40.de/I40/Navigation/EN/InPractice/Online-Library/online-library.html

3. Basic concepts for Industrie 4.0

Industrie 4.0 describes concepts and definitions for the domain of smart manufacturing. For Industrie 4.0, the term asset, being any "object which has a value for an organization", is of central importance [2, 23]. Thus, assets in Industrie 4.0 can take almost any form, for example be a production system, a product, a software installation, intellectual properties or even human resources.

According [23], the ”reference architecture model Industry 4.0 (RAMI4.0) provides a structured view of the main elements of an asset using a level model consisting of three axes […]. Complex interrelationships can thus be broken down into smaller, more manageable sections by combining all three axes at each point in the asset’s life to represent each relevant aspect.”

Assets shall have a logical representation in the "information world", for example shall be managed by IT-systems. Thus, an asset has to be precisely identified as an entity, shall have a "specific state within its life (at least a type or instance)", shall have communication capabilities, shall be represented by means of information and shall be able to provide technical functionality [23]. This logical representation of an asset is called Administration Shell [4]. The combination of asset and Administration Shell forms the so-called I4.0 Component. In international papers [18], the term smart manufacturing replaces the term Industrie 4.0.

For the large variety of assets in Industrie 4.0, the Administration Shell allows handling of these assets in the information world in always the same manner. This reduces complexity and allows for scalability. Additional motivation can be found in [2] [4] [7] [8].
4. The concept of properties

According [20], the “IEC 61360 series provides a framework and an information model for product dictionaries. The concept of product type is represented by ‘classes’ and the product characteristics are represented by ‘properties’.”

Such properties are standardized data elements. The definitions of such properties can be found in a range of repositories, such as IEC CDD (common data dictionary) or eCl@ss. The definition of a property (aka standardized data element type, property type) associates a worldwide unique identifier with a definition, which is a set of well-defined attributes. Relevant attributes for the Administration Shell are, amongst other, the preferred name, the symbol, the unit of measure and a human-readable textual definition of the property.

</tr>
</tbody>
</table>

The instantiation of such definition (just 'property', property instance) typically associates a value to the property. By this mechanism, semantically well-defined information can be conveyed by the Administration Shell.

Note: Industrie 4.0 and smart manufacturing in general will require many properties which are beyond the current scope of IEC CDD, eCl@ss or other repositories. It is expected, that these sets of properties will be introduced, as more and more domains are modelled and standardized (next clause).

5. The concept of submodels

"The Administration Shell is the standardized digital representation of the asset, corner stone of the interoperability between the applications managing the manufacturing systems" [18]. Thus, it needs to provide a minimal but sufficient description according to the different application scenarios in Industrie 4.0 [7] [8]. Many different (international) standards, consortium specifications and manufacturer specifications can already contribute to this description [18].

As the figure shows, information from different many different technical domains could be associated with a respective asset and thus, many different properties are required to be represented in Administration Shells of future I4.0 Components. In order to manage these complex set of information, submodels provide a separation of concern.
The Administration Shell is thus made up of a series of submodels [4]. These represent different aspects of the asset concerned; for example, they may contain a description relating to safety or security [14] but could also outline various process capabilities such as drilling or installation [6].

From the perspective of interoperability, the aim is to standardise only a single submodel for each aspect / technical domain. For example, it will thus be possible to find a drilling machine by searching for an Administration Shell containing a submodel “Drilling” with appropriate properties. For communication between different I4.0 components, certain properties can then be assumed to exist. In an example like this, a second submodel, “energy efficiency”, could then ensure that the drilling machine is able to cut its electricity consumption when it is not in operation.

Note: side benefit of the Administration Shell will be to simplify the update of properties from product design (and in particular system design) tools, update of properties from real data collected in the instances of assets, improve traceability of assets along life cycle and help certify assets from data.

6. Basic Structure of the Asset Administration Shell

The document on the Structure of the Asset Administration Shell [4] [18] presented a rough, logical view of the AssetAdministration Shell’s structure. The AssetAdministration Shell – shown in blue in the following figure – comprises different sets of information. Both, the asset and the Administration Shell are identified by a globally unique identifier. It comprises a number of submodels for a characterisation of the AssetAdministration Shell.
Properties, data and functions will also contain information which not every partner within a value-added network or even within an organisational unit should be able to access or whose integrity and availability should be guaranteed. Therefore the structure of the Administration Shell shall be able to handle aspects such as access protection, visibility, identity and rights management, confidentiality and integrity. Information security needs to be respected and has to be aligned with an overall security concept. Implementation of security must go together with the implementation of other components of an overall system.

Each submodel contains a structured quantity of properties that can refer to data and functions. A standardised format based on IEC 61360-1/ ISO 13584-42 is envisaged for the properties. Thus, property value definition shall follow the same principles as also ISO 29002-10 and IEC 62832-2. Data and functions may be available in various, complementary formats.

The properties of all the submodels therefore result in a constantly readable directory of the key information of the Administration Shell and thus of the I4.0 component. To enable binding semantics, Administration Shells, assets, submodels and properties must all be clearly identified. Permitted global identifiers are IRDI (e.g. in ISO TS 29002-5, eCl@ss and IEC Common Data Dictionaries) and URIs (Unique Resource Identifiers, e.g. for ontologies).

It should be possible to filter elements of the Administration Shell or submodels according to different given views (→ Example C.4 in [18]). This facilitates different perspectives or use-cases for the application of Administration Shell's information.
## 7. Requirements

This section collects the requirements from various documents that have impact on the specific structure of the Administration Shell. These requirements serve as input for the specific description of the structures of the Administration Shell.

The following requirements are taken from the document “Implementation strategy of Plattform Industrie 4.0” [2]. They are marked “STRAT”. The “Tracking” column validates the requirements by linking to features of the UML metamodel or this document in general.

<table>
<thead>
<tr>
<th>ID</th>
<th>Requirement</th>
<th>Tracking</th>
</tr>
</thead>
<tbody>
<tr>
<td>STRAT#1</td>
<td>A network of Industrie 4.0 components must be structured in such a way that connections between any end point (Industrie 4.0 components) are possible. The Industrie 4.0 components and their contents are to follow a common semantic model.</td>
<td>Network possible but not scope of this part of the document series. Common semantic model realized by domain specific submodels (HasSemantics/ ConceptDescription and by Relations)</td>
</tr>
<tr>
<td>STRAT#2</td>
<td>It must be possible to define the concept of an Industrie 4.0 component in such a way that it can meet requirements with different focal areas, i.e. “office floor” or “shop floor”.</td>
<td>Content-wise, many different submodels possible.</td>
</tr>
<tr>
<td>STRAT#3</td>
<td>Industrie 4.0 compliant communication must be performed in such a way that the data of a virtual representation of an Industrie 4.0 component can be kept either in the object itself or in a (higher level) IT system.</td>
<td>Metamodel and information representation independent of any deployment scenario.</td>
</tr>
<tr>
<td>STRAT#4</td>
<td>In the case of a virtual representation of an I4.0 component in a higher-level system, an integrity association must be ensured between the asset and its representation.</td>
<td>Integrity part of security approach.</td>
</tr>
<tr>
<td>STRAT#5</td>
<td>A suitable reference model must be established to describe how a higher level IT system can make the Administration Shell available in an Industrie 4.0 compliant manner (SOA approach, delegation principle).</td>
<td>Scope of upcoming part of the document series; not scope of this part.</td>
</tr>
<tr>
<td>STRAT#6</td>
<td>A description is required of how the Administration Shell can be “transported” from the originator (e.g. component manufacturer or electrical designer) to the higher level IT system (e.g. as an attachment to an email).</td>
<td>Hierarchical representation by XML/JSON and package file format allow for different transport scenarios.</td>
</tr>
<tr>
<td>STRAT#7</td>
<td>Depending on the nature of the higher level systems, it may be necessary for the administration objects to allow for deployment in more than one higher level IT system.</td>
<td>Metamodel and information representation independent of any deployment scenario.</td>
</tr>
<tr>
<td>STRAT#8</td>
<td>The Industrie 4.0 component, and in particular the Administration Shell, its inherent functionality and the protocols concerned are to be “encapsulation-capable” or “separable” from any field busses in use.</td>
<td>Metamodel and information representation independent of any communication scenario.</td>
</tr>
<tr>
<td>STRAT#9</td>
<td>The aim of the Industrie 4.0 component is to detect non-Industrie 4.0 compliant communication relationships leading to or from the object’s Administration Shell and to make them accessible to end-to-end engineering.</td>
<td>Non-Industrie 4.0 compliant communication relationships could be modelled by submodels and therefore made available.</td>
</tr>
<tr>
<td>STRAT#10</td>
<td>It should be possible to logically assign other Industrie 4.0 components to one Industrie 4.0 component (e.g. an entire machine) in such a way that there is (temporary) nesting.</td>
<td>References and preparations for Composite components [12] (not in scope of part 1)</td>
</tr>
<tr>
<td>STRAT#11</td>
<td>Higher level systems should be able to access all Industrie 4.0 components in a purpose-driven and restrictable manner, even when these are (temporarily) logically assigned.</td>
<td>Scope of upcoming part of the document series; not scope of this part.</td>
</tr>
<tr>
<td>STRAT#12</td>
<td>Characteristics (1) Identifiability</td>
<td>Given by Identifiable</td>
</tr>
</tbody>
</table>
The following requirements are taken from the document “The Structure of the Administration Shell: Trilateral perspectives from France, Italy and Germany” [18]. They are marked “tAAS”.

Note: The term “property” was used in a very broad sense in previous publications of the Plattform Industrie 4.0. The metamodel in this document distinguishes between properties in a more classical sense as data element like “maximum temperature” and other submodel elements like operations, events etc.

<table>
<thead>
<tr>
<th>Source</th>
<th>Requirement</th>
<th>Tracking</th>
</tr>
</thead>
</table>
| tAAS-#1 | The Administration Shell shall accept properties from different technical domains in mutually distinct submodels that can be version-controlled and maintained independently of each other. | Identifiable
AdministrativeInformation
Submodel |
| | | Requirements tAAS-#1 implicitly contains the requirements of versioning. Versioning is supported for all elements inheriting from Identifiable.

Requirement tAAS-#1 is fulfilled because several submodels per AAS are possible. Every submodel is identifiable and an Identifiable may contain administrative information (administrativeInformation) for versioning.

The reason for submodels to be identifiable is that they may be maintained independently of other submodels (Requirement tAAS-#1) and that they can be reused within different AAS. However, since submodel elements may refer to elements from other AAS dependencies have to be considered in parallel development and before reuse. |
<p>| tAAS-#2 | The Administration Shell should be capable of including properties from a wide range of technical domains and of [sic!] identify which domain they derive from. | HasSemantics |
| | | Via semantic references property definitions from different dictionaries and thus different domains can be used within submodels. |</p>
<table>
<thead>
<tr>
<th>tAAS-#3</th>
<th>For finding definitions within each relevant technical domain, different procedural models should be allowed that respectively meet the requirements of standards, consortium specifications and manufacturer specifications sets.</th>
</tr>
</thead>
<tbody>
<tr>
<td>tAAS-#4</td>
<td>Different Administration Shells in respect of an asset must be capable of referencing each other. In particular, elements of an Administration Shell should be able to play the role of a “copy” of the corresponding components from another Administration Shell.</td>
</tr>
<tr>
<td>tAAS-#5</td>
<td>Individual Administration Shells should, while retaining their structure, be combined into an overall Administration Shell.</td>
</tr>
<tr>
<td>tAAS-#6</td>
<td>Identification of assets, Administration Shells, properties and relationships shall be achieved using a limited set of identifiers (IRDI, URI and GUID), providing as far as possible offer global uniqueness.</td>
</tr>
<tr>
<td>tAAS-#7</td>
<td>The Administration Shell should allow retrieval of alternative identifiers such as a GS1 and GTIN identifier in return to asset ID (deferencing).</td>
</tr>
<tr>
<td>tAAS-#8</td>
<td>The Administration Shell consists of header and body.</td>
</tr>
</tbody>
</table>
| tAAS-#9 | The header contains information about the identification. | AssetAdministrationShell.asset  
The Asset Administrative Shell is representing an asset with a unique id.  
See also tAAS-#7  
See also tAAS-#13 |
| tAAS-#10 | The body contains information about the respective asset(s). | AssetAdministrationShell.submodels  
All submodels give information with respect to or related to the asset presented by the AAS.  
Note: An Asset Administration Shell is representing exactly one asset. In case of a Composite Asset Administration Shell it is implicitly representing several assets (see also tAAS-#5). |
| tAAS-#11 | The information and functionality in the Administration Shell is accessible by means of a standardised application programming interface (API). | Will be covered in future parts of the document series |
| tAAS-#12 | The Administration Shell has a unique ID. | AssetAdministrationShell.identification.id  
Since AssetAdministrationShell inherits from Identifiable Requirement tAAS-#12 is fulfilled. |
| tAAS-#13 | The asset has a unique ID. | Asset.identification.id  
Since Asset inherits from Identifiable Requirement tAAS-#13 is fulfilled.  
See also Requirement tAAS-#7.  
Since Asset does not contain any specific attributes mandatory and only suitable for sensors etc. also more complex assets like industrial facilities can be modelled (Requirement tAAS-#14). The only assumption is that the industrial facility also has a globally unique id.  
Note: See also Composite Asset Administration Shell (see tAAS-#5) that allows the modelling of complex assets consisting of other assets that are represented by an AAS each by themselves. |
| tAAS-#14 | An industrial facility is also an asset, it has an Administration Shell and is accessible by means of ID. | Asset  
Asset AdministrationShell.derivedFrom  
Since Asset does not contain any specific attributes mandatory and only suitable for sensors etc. also more complex assets like industrial facilities can be modelled. The only assumption is that the industrial facility also has a globally unique id.  
Note: See also Composite Asset Administration Shell (see tAAS-#5) that allows the modelling of complex assets consisting of other assets that are represented by an AAS each by themselves. |
| tAAS-#15 | Types and instances must be identified as such. | HasKind (with kind=Type or kind=Instance) for Asset  
AssetAdministrationShell.derivedFrom  
Since Asset does not contain any specific attributes mandatory and only suitable for sensors etc. also more complex assets like industrial facilities can be modelled. The only assumption is that the industrial facility also has a globally unique id.  
Note: See also Composite Asset Administration Shell (see tAAS-#5) that allows the modelling of complex assets consisting of other assets that are represented by an AAS each by themselves. |
Since Asset inherits from HasKind Requirement tAAS-#15 is fulfilled and asset types can be distinguished from asset instances.

Additionally a derivedFrom relationship can be established between the AAS for an asset instance and the AAS for the asset type.

| tAAS-#16 | The Administration Shell can include references to other Administration Shells or Smart Manufacturing information. | ReferenceElement  
|          |                                                      | File  
|          |                                                      | Blob  
|          | AssetAdministrationShell.derivedFrom                  | The derivedFrom relationship between two AAS is special and is for example used to establish a relationship between asset instances and the asset type.  
|          |                                                      | For composite AAS (see tAAS-#5) there also is the relationship to AAS the composite AAS is composed of.  
|          |                                                      | The ReferenceElement is very generic and can reference another AAS as well as information within another AAS or even some information that is completely outside any AAS (as long as it has a global unique id).  
|          |                                                      | Files and BLOB can be used as submodel elements to include very generic manufacturing information that is not or cannot be modelled via properties or the other submodel elements defined for the Asset Administration Shell. |

| tAAS-#17 | Additional properties, e. g. manufacturer specific, must be possible. | HasDataSpecification  
|          |                                                      | ConceptDictionary  
|          |                                                      | Via Data Specification Templates additional attributes for assets, properties and other submodel elements, submodels, views and even the AssetAdministration Shell itself can be defined and checked by tools.  
|          |                                                      | New proprietary property descriptions can be locally added to the local concept dictionary of the AAS and used for semantic definition in properties or other submodel elements.  
|          |                                                      | An extension of the metamodel by defining proprietary classes inheriting from the defined classes of this metamodel is also possible.  
|          |                                                      | Via API (see tAAS-#11) new properties, other submodel elements and submodels can be added – assumed the corresponding access permissions are given. |

| tAAS-#18 | A reliable minimum number of properties must be defined for each Administration Shell. | hasKind for Submodel and SubmodelElements  
|          |                                                      | A reliable minimum number of properties is defined by the metamodel itself. They are called (class) attributes.  
|          |                                                      | HasKind (with kind=Type) for Submodel and submodel elements enables the definition of submodel (element) types. These types are referenced via semanticId.  
|          |                                                      | Note: the term property within the metamodel has a special semantics and shall not be mixed with the implicitly available attributes of the different classes. Although these attributes as
The properties and other elements of information in the Administration Shell must be suitable for types and instances. All elements inheriting from `HasKind` can distinguish between types and instances. This is especially true for `SubmodelElement` and `Submodel`.

Note: Submodels or properties of `kind=Type` do not describe an asset of `kind=Type`. This is done via properties of `kind=Instance`.

**tAAS-#20**

There must be a capability of hierarchical and countable structuring of the properties.

Requirement tAAS-#20 is fulfilled by collections of data elements. The collection can be further characterized whether it is ordered and whether it may contain duplicates. Collections are built recursively and thus contain other submodel elements of the same AAS. For referencing properties or other submodel elements of other AAS a reference (`ReferenceElement`) or relationship element (`RelationshipElement`) needs to be included as part of the complex property.

**tAAS-#21**

Properties shall be able to reference other properties, even in other Administration Shells.

A reference element can either reference any other element that is referable (i.e. inheriting from `Referable`) within the same or another AAS. Or it can reference entities completely outside any AAS via its global id.

Note: For referencing elements within the same AAS it is not always necessary to use a reference property. Depending on the context also submodel element collections, relations etc. might be more suitable.

Within *operations* also other elements (that should have their own semantic reference, `OperationVariable`) are referenced or used as input or output argument.

**tAAS-#22**

Properties must be able to reference information and functions of the Administration Shell.

Functions in the sense of executable entities are represented as *operations*.

The following requirements have been derived from the document "Security of the Administrative Shell" [14]. They are marked as "SecAAS"
| SecAAS-#1 | Identification and authentication: It must be ensured that the correct entities (Administration Shell and users) interact with each other. This applies both in a local communication context (within a machine or plant) and in a global context (across companies). The clear identification (by authentication) of the communication partners is a basic requirement for the interaction with a management shell. Without them, further security features (confidentiality, integrity, etc.) cannot be guaranteed. | Security.trustAnchor
Certificate

Trust anchors are realized by certificates.
Certificate handling will be detailed in future parts or versions of the document (series). |

| SecAAS-#2 | User and rights management: An AssetAdministration Shell can have different interaction partners. To control the possibilities of interaction with the Administration Shell, a user and rights management is necessary. | Security.policyAdministrationPoint
AccessControl
AccessControl.accessPermissionRule

There is no explicit subject management in the AAS: It is assumed that the identity of the subject requesting access with a given role (via the API - see SecAAS-#11) is authenticated outside the AAS. The AAS can check the authorization via the endpoint to the subject attributes provider.

For every object in the Asset Administration Shell access permission rules can be defined. |

| SecAAS-#3 | Secure Communication: Communication with the Administrative Shell may include sensitive information. Likewise, a change in the communication between the Administration Shell and its communication partners can cause serious and dangerous disruptions in a machine or plant. It is therefore mandatory that adequate measures be taken to ensure communication security. This must be done by using appropriate security protocols. | Not applicable |

| SecAAS-#4 | Event logging: The traceability of interaction with the Administration Shell plays a crucial role in the detection of security incidents. This traceability is achieved through logging / event logging and auditing. The management shell must therefore provide methods that log accesses and changes in state of the management shell without modification. It is also important to be able to centrally collect and evaluate this event information. | History handling will be detailed in future parts or versions of the document (series). |
Annex B. Templates for UML Tables

In this annex, the templates used for element specification are explained.

### Template for document classes (elements):

<table>
<thead>
<tr>
<th>Class:</th>
<th>Explanation:</th>
<th>Inherits from:</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Attribute</strong> (*=mandatory)</td>
<td>Explanation</td>
<td>Type</td>
</tr>
<tr>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td></td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

Kind is defined with semantics of UML:
- attr: attribute (Type is no Object)
- aggr: aggregation (does not exist independent of its parent)
- ref: composition (does exist independent of its parent)

Additionally, there is kind:
- ref*: reference via “Reference” class with target=<Type>
- For more information on referencing see clause 3.6.15

Card. is the cardinality.

### Template for enumerations:

<table>
<thead>
<tr>
<th>Enumeration:</th>
<th>Explanation:</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Literal</strong></td>
<td>Explanation</td>
</tr>
<tr>
<td></td>
<td></td>
</tr>
</tbody>
</table>
Annex C. Legend for UML Modelling

Figure 59 Aggregation in Metamodel in UML – Legend

Figure 60 Association in Metamodel in UML - Legend

Figure 61 Composition in Metamodel in UML - Legend

Figure 62 Identification in Metamodel in UML - Legend
Figure 63 Inheritance Classes in Metamodel in UML - Legend

Figure 64 Inheritance Enumerations in Metamodel in UML - Legend
Annex D. Metamodel UML with inherited Attributes

In this annex some UML diagrams are shown together with all inherited attributes. See also Figure 29 for a diagram with all inherited attributes of ConceptDescription.

Figure 65 Core Model with inherited Attributes
Figure 66: Access Control with inherited attributes
### Figure 67 Submodel Element Collection with inheritance

**Class Diagram**

The diagram illustrates the relationships and properties of submodel element collections. It shows the inheritance and association between classes, with specific details for properties such as semanticId, qualifier, hasDataSpecification, kind, idShort, category, description, and parent relationships.
Annex E. XML schemas and complete example

1. XML Schemas for Administration Shell

The schema is split into two parts:

- The main concepts of the Administration Shell (AAS.xsd)
- The Data Specification Template IEC61360 (IEC616360.xsd)

Subsequently, an example in XML is discussed.

2. Schema for overall Administration Shell

```xml
<?xml version="1.0" encoding="UTF-8"?>
<schema targetNamespace="http://www.admin-shell.io/aas/1/0"
  elementFormDefault="qualified" xmlns="http://www.w3.org/2001/XMLSchema"
  <import schemaLocation="IEC61360.xsd" namespace="http://www.admin-shell.io/IEC61360/1/0"/>
</schema>
```

```xml
<complexType name="aasenv_t">
  <sequence>
    <element name="assetAdministrationShells" type="aas:assetAdministrationShells_t" minOccurs="0" maxOccurs="1"></element>

3. AAS IEC61360 Datatype

For IEC 61360, a data specification is made available, individually:

```xml
<complexType name="dataSpecificationIEC61360_t">
  <xsd:sequence>
    <xsd:element ref="IEC61360:preferredName" maxOccurs="1" minOccurs="1"/>
    <xsd:element ref="IEC61360:shortName" maxOccurs="1" minOccurs="0"/>
    <xsd:element ref="IEC61360:unit" maxOccurs="1" minOccurs="0"/>
    <xsd:element ref="IEC61360:unitId" maxOccurs="1" minOccurs="0"/>
    <xsd:element ref="IEC61360:valueFormat" maxOccurs="1" minOccurs="0"/>
    <xsd:element ref="IEC61360:sourceOfDefinition" maxOccurs="1" minOccurs="0"/>
    <xsd:element ref="IEC61360:symbol" maxOccurs="1" minOccurs="0"/>
    <xsd:element ref="IEC61360:dataType" maxOccurs="1" minOccurs="0"/>
    <xsd:element ref="IEC61360:definition" maxOccurs="1" minOccurs="0"/>
    <xsd:element ref="IEC61360:valueList" maxOccurs="1" minOccurs="0"/>
    <xsd:element ref="IEC61360:code" maxOccurs="1" minOccurs="0"/>
  </xsd:sequence>
</complexType>
```
4. XML Example

For cross reference, a complete self-contained example is given, which relates to the unified example in clause 4.3.

```xml
<?xml version="1.0" encoding="UTF-8"?>

Annex F. JSON schema and complete examples

1. JSON Schema for Administration Shell

The following schema uses JSON Schema\(^{28}\) in draft version 04 to allow for validation of JSON files.

Note: this schema is a core model; as of November 2018, it does not feature the security model, views and selected SubmodelElements.

Table 17 JSON schema

```json
{
  "$schema": "http://json-schema.org/draft-04/schema#",
  "title": "AssetAdministrationShellEnvironment",
  "type": "object",
